

# Package ‘contact’

May 17, 2021

**Title** Creating Contact and Social Networks

**Version** 1.2.8

**Description** Process spatially- and temporally-discrete data into contact and social networks, and facilitate network analysis by randomizing individuals' movement paths and/or related categorical variables. To use this package, users need only have a dataset containing spatial data (i.e., latitude/longitude, or planar x & y coordinates), individual IDs relating spatial data to specific individuals, and date/time information relating spatial locations to temporal locations. The functionality of this package ranges from data “cleaning” via multiple filtration functions, to spatial and temporal data interpolation, and network creation and analysis. Functions within this package are not limited to describing interpersonal contacts. Package functions can also identify and quantify “contacts” between individuals and fixed areas (e.g., home ranges, water bodies, buildings, etc.). As such, this package is an incredibly useful resource for facilitating epidemiological, ecological, ethological and sociological research.

**Depends** R (>= 3.6.0)

**Imports** ape (>= 5.3), data.table (>= 1.12.2), doParallel (>= 1.0.15),  
foreach (>= 1.4.8), igraph (>= 1.2.4.1), lubridate (>= 1.7.4),  
parallel (>= 3.6.0), raster (>= 2.9-5), rgdal (>= 1.4-4), rgeos  
(>= 0.4-3), sp (>= 1.3-1), stats (>= 3.6.0)

**License** CC0

**Encoding** UTF-8

**LazyData** true

**RoxygenNote** 7.1.1

**BugReports** <https://github.com/lanzaslab/contact/issues>

**Suggests** knitr, rmarkdown

**VignetteBuilder** knitr

**NeedsCompilation** no

**Author** Trevor Farthing [aut, cre],  
Daniel Dawson [aut],  
Cristina Lanzas [ctb]

**Maintainer** Trevor Farthing <tsfarthi@ncsu.edu>

**Repository** CRAN

**Date/Publication** 2021-05-17 16:40:11 UTC

baboons

*Real-time location data for 19 baboons*

---

## Description

A dataset containing geographic real-time point locations for 19 baboons observed between 03:00:00 and 04:00:00 UTC on August 13th 2012, and are included here primarily to be used for function-testing purposes.

## Usage

```
data(baboons)
```

## Format

A data frame with 65140 rows and 5 variables:

**timestamp** The date and time a sensor measurement was taken. Time units are in UTC (Coordinated Universal Time) or GPS time, which is a few leap seconds different from UTC.

**location.long** The geographic longitude of a location along an animal track as estimated by the processed sensor data. Positive values are east of the Greenwich Meridian, negative values are west of it. Presented as decimal degrees based on the WGS84 reference system.

**location.lat** The geographic latitude of a location along an animal track as estimated by the processed sensor data. Positive values are north of the equator, negative values are west of it. Presented as decimal degrees based on the WGS84 reference system.

**individual.local.identifier** A unique individual identifier for the animal, provided by the data owner.

**dateTime** The date and time, rounded to the nearest second that a sensor measurement was taken. Derived from timestamps. Note that this variable is not present in the source data set.

## Details

This data file a subset of a larger one published by the Movebank Data Repository ([www.datarepository.movebank.org](http://www.datarepository.movebank.org)). The larger data set on Movebank contains baboon locations between 08/01/2012 and 08/14/2012. As of the time of publication of this package, a version of the published animal tracking data set can be viewed on Movebank ([www.movebank.org](http://www.movebank.org)) in the study "Collective movement in wild baboons (data from Strandburg-Peshkin et al. 2015)". Individual attributes in the data files are defined here and in the Movebank Attribute Dictionary, available at [www.movebank.org/node/2381](http://www.movebank.org/node/2381).

The item descriptions described herein appear in the README text provided for the repository entry verbatim.

Note that according to data publishers, "this dataset does not include interpolated locations or locations that failed the speed filter (see Strandburg-Peshkin et al. 2015 for details)."

---

calves

*Real-time location data for 10 calves on May 2nd 2016*

---

## Description

A dataset containing planar real-time point locations for 10 calves between 00:00:00 and 02:00:00 UTC on May 2nd, 2016. These data are a subset of the data set published in the supplemental materials of Dawson et al. 2019, and are included here primarily to be used for function-testing purposes.

## Usage

```
data(calves)
```

## Format

A data frame with 11118 rows and 5 variables:

**calftag** a unique identifier for each calf

**x** planar x coordinate

**y** planar y coordinate

**time** UTC time at which location fix was obtained

**date** date on which fix location occurred

## Details

Calves were approximately 1.5-year-old beef cattle kept in a 30 X 35 m<sup>2</sup> pen at the Kansas State University Beef Cattle Research Center in Manhattan, KS.

Data collection was supported by U.S. National Institute of Health (NIH) grant R01GM117618 as part of the joint National Science Foundation-NIH-United States Department of Agriculture Ecology and Evolution of Infectious Disease program.

---

calves2018

*Real-time location data for 20 calves in June 2018*

---

## Description

A dataset containing planar real-time point locations for 20 calves between 00:00:00 on June 1st, 2018 and 23:59:59 UTC on June 3, 2018.

## Usage

```
data(calves2018)
```

## Format

A data frame with 193551 rows and 4 variables:

**calftag** a unique identifier for each calf

**x** planar x coordinate

**y** planar y coordinate

**dateTime** UTC date and time at which location fix was obtained

## Details

Calves were approximately 1.5-year-old castrated male cattle (i.e., steer) kept in a 30 X 35 m<sup>2</sup> pen at the Kansas State University Beef Cattle Research Center in Manhattan, KS.

Data collection was supported by U.S. National Institute of Health (NIH) grant R01GM117618 as part of the joint National Science Foundation-NIH-United States Department of Agriculture Ecology and Evolution of Infectious Disease program.

## Examples

data("calves2018") #alternatively, you may use the command: contact::calves2018
head(calves2018)
```

---

 confine

*Identify and Remove Data Points Outside of a Specified Area*

---

### Description

Identifies and removes timepoints when tracked individuals were observed outside of a defined polygon (note: the polygon should be described by the vectors `confinementCoord.x` (x coordinates) and `confinementCoord.y` (y coordinates)). These vectors must be the same length and the coordinates should be listed in the clockwise or counter-clockwise order that they are observed on the confining polygon.

### Usage

```
confine(
  x,
  point.x = NULL,
  point.y = NULL,
  confinementCoord.x,
  confinementCoord.y,
  filterOutput = TRUE
)
```

### Arguments

<code>x</code>	Data frame or non-data-frame list that will be filtered.
<code>point.x</code>	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in <code>x</code> , that denotes what planar-x or longitude coordinate information will be used. If argument <code>== NULL</code> , the function assumes a column with the colname "x" exists in <code>x</code> . Defaults to <code>NULL</code> .
<code>point.y</code>	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in <code>x</code> , that denotes what planar-y or latitude coordinate information will be used. If argument <code>== NULL</code> , the function assumes a column with the colname "y" exists in <code>x</code> . Defaults to <code>NULL</code> .
<code>confinementCoord.x</code>	Vector describing x-coordinates of confining-polygon vertices. Each vertex should be described in clockwise or counter-clockwise order, and ordering should be consistent with <code>confinementCoord.y</code> .
<code>confinementCoord.y</code>	Vector describing y-coordinates of confining-polygon vertices. Each vertex should be described in clockwise or counter-clockwise order, and ordering should be consistent with <code>confinementCoord.x</code> .
<code>filterOutput</code>	Logical. If <code>TRUE</code> , output will be a data frame or list of data frames (depending on whether or not <code>x</code> is a data frame or not) containing only points within confinement polygons. If <code>FALSE</code> , no observations are removed and a "confinement_status" column is appended to <code>x</code> , detailing the relationship of each point to the confinement polygon. Defaults to <code>TRUE</code> .

## Details

If users are not actually interested in filtering datasets, but rather, determining what observations should be filtered, they may set `filterOutput == FALSE`. By doing so, this function will append a "confinement\_status" column to the output dataframe, which reports the results of `sp::point.in.polygon` function that is used to determine if individuals are confined within a given polygon. In this column, values are: 0: point is strictly exterior to pol; 1: point is strictly interior to pol; 2: point lies on the relative interior of an edge of pol; 3: point is a vertex of pol (see `?sp::point.in.polygon`).

## Value

If `filterOutput == TRUE`, returns `x` less observations where points were located outside of the polygon defined by points in `confinementCoord.x` and `confinementCoord.y`.

If `filterOutput == FALSE`, returns `x` appended with a "confinement\_status" column which reports the results of `sp::point.in.polygon` function, which is used to determine if observed points are confined within the polygon defined by points in `confinementCoord.x` and `confinementCoord.y`.

## Examples

```
data("calves")

water_trough.x<- c(61.43315, 61.89377, 62.37518, 61.82622) #water polygon x-coordinates
water_trough.y<- c(62.44815, 62.73341, 61.93864, 61.67411) #water polygon y-coordinates

headWater1<- confine(calves, point.x = calves$x, point.y = calves$y,
  confinementCoord.x = water_trough.x, confinementCoord.y = water_trough.y,
  filterOutput = TRUE) #creates a data set comprised ONLY of points within the water polygon.

headWater2<- confine(calves, point.x = calves$x, point.y = calves$y,
  confinementCoord.x = water_trough.x, confinementCoord.y = water_trough.y,
  filterOutput = FALSE) #appends the "confinement_status" column to x.
```

---

contact-defunct

*Defunct functions in contact*

---

## Description

These functions have been removed from our package.

## Details

- **contactTest**: `contactTest` is defunct and was removed in version 1.2.0. Please consider using another contact-comparison function instead (e.g., `contactCompare_chisq`, `contactCompare_mantel`, etc.)"

---

contactCompare\_binom *Exact Binomial Test for Comparing Observed Contacts to a Random Distribution*

---

## Description

This function is used to determine if tracked individuals in an empirical dataset had more or fewer contacts with other tracked individuals/specified locations than would be expected at random. The function works by comparing an empirical contact distribution (generated using `x.summary` and `x.potential`) to a NULL distribution (generated using `y.summary` and `y.potential`) using an exact binomial goodness-of-fit test. Note here, the NULL hypothesis is that empirical data are consistent with the NULL distribution, and the alternative hypothesis is that the data are NOT consistent. This function SHOULD NOT be used to compare two empirical networks, as the function assumes `x.summary` and `y.summary` represent observed and expected values, respectively. Please note that this is a function of convenience that is essentially a wrapper for the `binom.test` function, that allows users to easily compare contact networks created using our pipeline of `contact::` functions.

This function was inspired by the methods described by Spiegel et al. 2016. They determined individuals to be expressing social behavior when nodes had greater degree values than would be expected at random, with randomized contact networks derived from movement paths randomized according to their novel methodology (that can be implemented using our `randomizePaths` function). Here, users can also identify when more or fewer contacts (demonstrated by the sign of values in the "difference" column in the output) with specific individuals than would be expected at random, given a pre-determined p-value threshold. Such relationships suggest social affinities or aversions, respectively, may exist between specific individuals.

Note: The default tested column (i.e., categorical data column from which data is drawn to be compared to randomized sets herein) is "id." This means that contacts involving each individual (defined by a unique "id") will be compared to randomized sets. Users may not use any data column for analysis other than "id." If users want to use another categorical data column in analyses rather than "id," we recommend re-processing data (starting from the `dist.all/distToArea` functions), while specifying this new data as an "id." For example, users may annotate an illness status column to the empirical input, wherein they describe if the tracked individual displayed gastrointestinal ("gastr"), respiratory ("respr"), both ("both"), illness symptoms, or were consistently healthy ("hel") over the course of the tracking period. Users could set this information as the "id," and carry it forward as such through the data-processing pipeline. Ultimately, they could determine if each of these disease states affected contact rates, relative to what would be expected at random.

Take care to ensure that the same `shuffle.type` is denoted as was originally used to randomize individuals' locations (assuming the `randomizePaths` function was used to do so). This is important for two reasons: 1.) If there was no `y.potential` input, the function assumes that `x.potential` is relevant to the random set as well. This is a completely fair assumption when `importBlocks == FALSE` or when the `shuffleUnit == 0`. In cases when the `shuffle.type` is 1 or 2, however, this assumption can lead to erroneous results and/or errors in the function. 2.) In the `randomizePaths` function, setting `shuffle.type == 2` produces only 1 `shuffle.unit`'s worth of data (e.g., 1 day), rather than a dataset with the same length of `x`. As such, there may be a different number of blocks in `y` compared to `x`. Here we assume that the mean randomized durations per block in `y.summary` and `y.potential`, are representative of mean randomized durations per block across each shuffle unit (e.g., day 1 is representative of day 3, etc.).

**Usage**

```

contactCompare_binom(
  x.summary,
  y.summary,
  x.potential,
  y.potential = NULL,
  importBlocks = FALSE,
  shuffle.type = 1,
  pairContacts = TRUE,
  totalContacts = TRUE,
  popLevelOutput = FALSE,
  parallel = FALSE,
  nCores = (parallel::detectCores()/2),
  ...
)

```

**Arguments**

<code>x.summary</code>	List or single-data frame output from the <code>summarizeContacts</code> function referring to the empirical data. Note that if <code>x.summary</code> is a list of data frames, only the first data frame will be used in the function.
<code>y.summary</code>	List or single-data frame output from the <code>summarizeContacts</code> function referring to the randomized data (i.e., NULL model contact-network edge weights). Note that if <code>y.summary</code> is a list of data frames, only the first data frame will be used in the function.
<code>x.potential</code>	List or single-data frame output from the <code>potentialDurations</code> function referring to the empirical data. Note that if <code>x.potential</code> is a list of data frames, potential contact durations used in the function will be determined by averaging those reported in each list entry.
<code>y.potential</code>	List or single-data frame output from the <code>potentialDurations</code> function referring to the randomized data. Note that if <code>y.potential</code> is a list of data frames, potential contact durations used in the function will be determined by averaging those reported in each list entry. If NULL, reverts to <code>x.potential</code> . Defaults to NULL.
<code>importBlocks</code>	Logical. If true, each block in <code>x.summary</code> will be analyzed separately. Defaults to FALSE. Note that the "block" column must exist in <code>.summary</code> AND <code>.potential</code> objects, and values must be identical (i.e., if block 100 exists in <code>x</code> inputs, it must also exist in <code>y</code> inputs), otherwise an error will be returned.
<code>shuffle.type</code>	Integer. Describes which <code>shuffle.type</code> (from the <code>randomizePaths</code> function) was used to randomize the <code>y.summary</code> data set(s). Takes the values "0," "1," or "2." This is important because there are different assumptions associated with each <code>shuffle.type</code> .
<code>pairContacts</code>	Logical. If TRUE individual id columns from <code>x.summary</code> and <code>y.summary</code> inputs will be included in analyses. Defaults to TRUE.
<code>totalContacts</code>	Logical. If TRUE <code>totalDegree</code> and <code>totalContactDurations</code> columns from <code>x.summary</code> and <code>y.summary</code> inputs will be included in analyses. Defaults to TRUE.

popLevelOutput	Logical. If TRUE a secondary output describing population-level comparisons will be appended to the standard, individual-level function output.
parallel	Logical. If TRUE, sub-functions within the summarizeContacts wrapper will be parallelized. Note that the only sub-function parallelized here is called ONLY when importBlocks == TRUE.
nCores	Integer. Describes the number of cores to be dedicated to parallel processes. Defaults to half of the maximum number of cores available (i.e., (parallel::detectCores()/2)).
...	Other arguments to be passed to the binom.test function.

### Value

Output format is dependent on popLevelOutput value.

If popLevelOut == FALSE output will be a single two data frame containing individual-level pairwise analyses of node degree, total edge weight (i.e., the sum of all observed contacts involving each individual), and specific dyad weights (e.g., contacts between individuals 1 and 2). The data frame contains the following columns:

id	the id of the specific individual.
metric	designation of what is being compared (e.g., totalDegree, totalContactDurations, individual 2, etc.). Content will change depending on which data frame is being observed.
method	Statistical test used to determine significance.
probEstimate	Probability of "successful" contact events.
p.val	p.values associated with each comparison.
contactDurations.x	Describes the number of observed events in x.summary.
contactDurations.y	Describes the number of observed events in y.summary.
noContactDurations.x	Describes the number of empirical events that were not observed given the total number of potential events in x.potential.
noContactDurations.y	Describes the number of random events that were not observed given the total number of potential events in y.potential.
difference	The absolute value given by subtracting contactDurations.y from contactDurations.x.
warning	Denotes if any specific warning occurred during analysis.
block.x	Denotes the specific time block from x.(Only if importBlocks == TRUE)
block.start.x	Denotes the specific timepoint at the beginning of each time block. (Only if importBlocks == TRUE)
block.end.x	Denotes the specific timepoint at the end of each time block. (Only if importBlocks == TRUE)
block.y	Denotes the specific time block from y.(Only if importBlocks == TRUE)

- `block.start.y` Denotes the specific timepoint at the beginning of each time block. (Only if `importBlocks == TRUE`)
- `block.end.y` Denotes the specific timepoint at the end of each time block. (Only if `importBlocks == TRUE`)

If `popLevelOutput == TRUE`, output will be a list of two data frames: The one described above, and second describing the population-level comparisons. Columns in each data frame are identical.

---

contactCompare\_chisq    *Compare Observed Contacts to a Random Distribution Using Chi-Square GoF*

---

## Description

This function is used to determine if tracked individuals in an empirical dataset had more or fewer contacts with other tracked individuals/specified locations than would be expected at random. The function works by comparing an empirical contact distribution (generated using `x.summary` and `x.potential`) to a NULL distribution (generated using `y.summary` and `y.potential`) using a X-square goodness-of-fit test. Note that here, the NULL hypothesis is that empirical data are consistent with the NULL distribution, and the alternative hypothesis is that the data are NOT consistent. This function SHOULD NOT be used to compare two empirical networks using Chi-squared tests, as the function assumes `x.summary` and `y.summary` represent observed and expected values, respectively. Please note that this is a function of convenience that is essentially a wrapper for the `chisq.test` function, that allows users to easily compare contact networks created using our pipeline of `contact::` functions.

This function was inspired by the methods described by Spiegel et al. 2016. They determined individuals to be expressing social behavior when nodes had greater degree values than would be

expected at random, with randomized contact networks derived from movement paths randomized according to their novel methodology (that can be implemented using our `randomizePaths` function). Here, users can also identify when more or fewer contacts (demonstrated by the sign of values in the "difference" column in the output) with specific individuals than would be expected at random, given a pre-determined p-value threshold. Such relationships suggest social affinities or aversions, respectively, may exist between specific individuals.

Note: The default tested column (i.e., categorical data column from which data is drawn to be compared to randomized sets herein) is "id." This means that contacts involving each individual (defined by a unique "id") will be compared to randomized sets. Users may not use any data column for analysis other than "id." If users want to use another categorical data column in analyses rather than "id," we recommend re-processing data (starting from the `dist.all/distToArea` functions), while specifying this new data as an "id." For example, users may annotate an illness status column to the empirical input, wherein they describe if the tracked individual displayed gastrointestinal ("gastr"), respiratory ("respr"), both ("both"), illness symptoms, or were consistently healthy ("hel") over the course of the tracking period. Users could set this information as the "id," and carry it forward as such through the data-processing pipeline. Ultimately, they could determine if each of these disease states affected contact rates, relative to what would be expected at random.

Take care to ensure that the same `shuffle.type` is denoted as was originally used to randomize individuals' locations (assuming the `randomizePaths` function was used to do so). This is important for two reasons: 1.) If there was no `y.potential` input, the function assumes that `x.potential` is relevant to the random set as well. This is a completely fair assumption when `importBlocks == FALSE` or when the `shuffleUnit == 0`. In cases when the `shuffle.type` is 1 or 2, however, this assumption can lead to erroneous results and/or errors in the function. 2.) In the `randomizePaths` function, setting `shuffle.type == 2` produces only 1 `shuffle.unit`'s worth of data (e.g., 1 day), rather than a dataset with the same length of `x`. As such, there may be a different number of blocks in `y` compared to `x`. Here we assume that the mean randomized durations per block in `y.summary` and `y.potential`, are representative of mean randomized durations per block across each shuffle unit (e.g., day 1 is representative of day 3, etc.).#'

Finally, if X-square expected values will be very small, approximations of p may not be correct (and in fact, all estimates will be poor). It may be best to weight these tests differently. In the event that this is the case, `contactCompare_binom` may be used to obtain more-accurate estimates.

## Usage

```
contactCompare_chisq(
  x.summary,
  y.summary,
  x.potential,
  y.potential = NULL,
  importBlocks = FALSE,
  shuffle.type = 1,
  pairContacts = TRUE,
  totalContacts = TRUE,
  popLevelOutput = FALSE,
  parallel = FALSE,
  nCores = (parallel::detectCores()/2),
  ...
)
```

**Arguments**

<code>x.summary</code>	List or single-data frame output from the <code>summarizeContacts</code> function referring to the empirical data. Note that if <code>x.summary</code> is a list of data frames, only the first data frame will be used in the function.
<code>y.summary</code>	List or single-data frame output from the <code>summarizeContacts</code> function referring to the randomized data (i.e., NULL model contact-network edge weights). Note that if <code>y.summary</code> is a list of data frames, only the first data frame will be used in the function.
<code>x.potential</code>	List or single-data frame output from the <code>potentialDurations</code> function referring to the empirical data. Note that if <code>x.potential</code> is a list of data frames, potential contact durations used in the function will be determined by averaging those reported in each list entry.
<code>y.potential</code>	List or single-data frame output from the <code>potentialDurations</code> function referring to the randomized data. Note that if <code>y.potential</code> is a list of data frames, potential contact durations used in the function will be determined by averaging those reported in each list entry. If NULL, reverts to <code>x.potential</code> . Defaults to NULL.
<code>importBlocks</code>	Logical. If true, each block in <code>x.summary</code> will be analyzed separately. Defaults to FALSE. Note that the "block" column must exist in <code>.summary</code> AND <code>.potential</code> objects, and values must be identical (i.e., if block 100 exists in <code>x</code> inputs, it must also exist in <code>y</code> inputs), otherwise an error will be returned.
<code>shuffle.type</code>	Integer. Describes which <code>shuffle.type</code> (from the <code>randomizePaths</code> function) was used to randomize the <code>y.summary</code> data set(s). Takes the values "0," "1," or "2." This is important because there are different assumptions associated with each <code>shuffle.type</code> .
<code>pairContacts</code>	Logical. If TRUE individual id columns from <code>x.summary</code> and <code>y.summary</code> inputs will be included in analyses. Defaults to TRUE.
<code>totalContacts</code>	Logical. If TRUE <code>totalDegree</code> and <code>totalContactDurations</code> columns from <code>x.summary</code> and <code>y.summary</code> inputs will be included in analyses. Defaults to TRUE.
<code>popLevelOutput</code>	Logical. If TRUE a secondary output describing population-level comparisons will be appended to the standard, individual-level function output.
<code>parallel</code>	Logical. If TRUE, sub-functions within the <code>summarizeContacts</code> wrapper will be parallelized. Note that the only sub-function parallelized here is called ONLY when <code>importBlocks == TRUE</code> .
<code>nCores</code>	Integer. Describes the number of cores to be dedicated to parallel processes. Defaults to half of the maximum number of cores available (i.e., <code>(parallel::detectCores()/2)</code> ).
<code>...</code>	Other arguments to be passed to the <code>chisq.test</code> function.

**Value**

Output format is dependent on `popLevelOutput` value.

If `popLevelOut == FALSE` output will be a single two data frame containing individual-level pairwise analyses of node degree, total edge weight (i.e., the sum of all observed contacts involving each individual), and specific dyad weights (e.g., contacts between individuals 1 and 2). The data frame contains the following columns:

id	the id of the specific individual.
metric	designation of what is being compared (e.g., totalDegree, totalContactDurations, individual 2, etc.). Content will change depending on which data frame is being observed.
method	Statistical test used to determine significance.
X.squared	Test statistic associated with the comparison.
p.val	p.values associated with each comparison.
df	Degrees of freedom associated with the statistical test.
contactDurations.x	Describes the number of observed events in x.summary.
contactDurations.y	Describes the number of observed events in y.summary.
noContactDurations.x	Describes the number of empirical events that were not observed given the total number of potential events in x.potential.
noContactDurations.y	Describes the number of random events that were not observed given the total number of potential events in y.potential.
difference	The absolute value given by subtracting contactDurations.y from contactDurations.x.
warning	Denotes if any specific warning occurred during analysis.
block.x	Denotes the specific time block from x.(Only if importBlocks == TRUE)
block.start.x	Denotes the specific timepoint at the beginning of each time block. (Only if importBlocks == TRUE)
block.end.x	Denotes the specific timepoint at the end of each time block. (Only if importBlocks == TRUE)
block.y	Denotes the specific time block from y.(Only if importBlocks == TRUE)
block.start.y	Denotes the specific timepoint at the beginning of each time block. (Only if importBlocks == TRUE)
block.end.y	Denotes the specific timepoint at the end of each time block. (Only if importBlocks == TRUE)

If popLevelOutput == TRUE, output will be a list of two data frames: The one described above, and second describing the population-level comparisons. Columns in each data frame are identical.

---

contactCompare\_mantel *Statistically Compare Two Contact Matrices*

---

### Description

Tests for similarity of the x.summary input to y.summary. Please note that this is a function of convenience that is essentially a wrapper for the ape::mantel.test function, that allows users to easily compare contact networks created using our pipeline of contact:: functions. Please understand that ape::mantel.test does not allow for missing values in matrices, so all NAs will be treated as zeroes.

### Usage

```
contactCompare_mantel(
  x.summary,
  y.summary,
  numPermutations = 1000,
  alternative.hyp = "two.sided",
  importBlocks = FALSE
)
```

### Arguments

x.summary	List or single-data frame output from the summarizeContacts function referring to the empirical data. Note that if x.summary is a list of data frames, only the first data frame will be used in the function.
y.summary	List or single-data frame output from the summarizeContacts function referring to the randomized data (i.e., NULL model contact-network edge weights). Note that if y.summary is a list of data frames, only the first data frame will be used in the function.
numPermutations	Integer. Number of times to permute the data. Defaults to 1000.
alternative.hyp	Character string. Describes the nature of the alternative hypothesis being tested when test == "mantel." Takes the values "two.sided," "less," or "greater." Defaults to "two.sided."
importBlocks	Logical. If true, each block in x.summary will be analyzed separately. Defaults to FALSE. Note that the "block" column must exist in .summary objects AND values must be identical (i.e., if block 100 exists in x.summary, it must also exist in y.summary), otherwise an error will be returned.

**Value**

Output format is a single data frame with the following columns.

method	Statistical test used to determine significance.
z.val	z statistic.
p.value	p.values associated with each comparison.
x.mean	mean contacts in x.summary overall or by block (if applicable). Note that these means are calculated BEFORE any NAs are converted to zeroes (see note above)
y.mean	mean contacts in y.summary overall or by block (if applicable). Note that these means are calculated BEFORE any NAs are converted to zeroes (see note above)
alternative.hyp	The nature of the alternative hypothesis being tested.
nperm	Number of permutations used to generate p value.
warning	Denotes if any specific warning occurred during analysis.

```

---

 contactDur.all

*Identify Inter-animal Contacts*

---

## Description

This function uses the output from `dist2All` to determine when and for how long tracked individuals are in "contact" with one another. Individuals are said to be in a "contact" event if they are observed within a given distance ( $\leq \text{dist.threshold}$ ) at a given timestep. Contacts are broken when individuals are observed outside the specified distance threshold from one another for  $> \text{sec.threshold}$  seconds. `Sec.threshold` dictates the maximum amount of time between concurrent observations during which potential "contact" events remain unbroken. For example, if `sec.threshold == 10`, only "contacts" occurring within 10secs of one another will be regarded as a single "contact" event of duration `sum(h)`. If in this case, a time difference between contacts was 11 seconds, the function will report two separate contact events.

The output of this function is a data frame containing a time-ordered contact edge set detailing inter-animal contacts.

## Usage

```

contactDur.all(
  x,
  dist.threshold = 1,
  sec.threshold = 10,
  blocking = FALSE,

```

```

    blockLength = 1,
    blockUnit = "hours",
    blockingStartTime = NULL,
    equidistant.time = FALSE,
    parallel = FALSE,
    nCores = (parallel::detectCores()/2),
    reportParameters = TRUE
  )

```

### Arguments

x	Output from the dist2All function. Can be either a data frame or non-data-frame list.
dist.threshold	Numeric. Radial distance (in meters) within which "contact" can be said to occur. Defaults to 1. Note: If you are defining contacts as occurring when polygons intersect, set dist.threshold to 0.
sec.threshold	Numeric. Dictates the maximum amount of time between concurrent observations during which potential "contact" events remain unbroken. Defaults to 10.
blocking	Logical. If TRUE, contacts will be evaluated for temporal blocks spanning blockLength blockUnit (e.g., 6 hours) within the data set. Defaults to FALSE.
blockLength	Integer. Describes the number blockUnits within each temporal block. Defaults to 1.
blockUnit	Character string taking the values, "secs," "mins," "hours," "days," or "weeks." Describes the temporal unit associated with each block. Defaults to "hours."
blockingStartTime	Character string or date object describing the date OR dateTime starting point of the first time block. For example, if blockingStartTime = "2016-05-01" OR "2016-05-01 00:00:00", the first timeblock would begin at "2016-05-01 00:00:00." If NULL, the blockingStartTime defaults to the minimum dateTime point in x. Note: any blockingStartTime MUST precede or be equivalent to the minimum timepoint in x. Additional note: If blockingStartTime is a character string, it must be in the format ymd OR ymd hms.
equidistant.time	Logical. If TRUE, location fixes in individuals' movement paths are temporally equidistant (e.g., all fix intervals are 30 seconds). Defaults to FALSE. Note: This is a time-saving argument. A sub-function here calculates the time difference (dt) between each location fix. If all fix intervals in an individuals' path are identical, it saves a lot of time.
parallel	Logical. If TRUE, sub-functions within the contactDur.all wrapper will be parallelized. Defaults to FALSE.
nCores	Integer. Describes the number of cores to be dedicated to parallel processes. Defaults to half of the maximum number of cores available (i.e., (parallel::detectCores()/2)).
reportParameters	Logical. If TRUE, function argument values will be appended to output data frame(s). Defaults to TRUE.

**Value**

Returns a data frame (or list of data frames if `x` is a list of data frames) with the following columns:

<code>dyadMember1</code>	The unique ID of an individual observed in contact with a specified second individual.
<code>dyadMember2</code>	The unique ID of an individual observed in contact with <code>dyadMember1</code> .
<code>dyadID</code>	The unique dyad ID used to identify the pair of individuals <code>dyadMember1</code> and <code>dyadMember2</code> .
<code>contactDuration</code>	The number of sequential timepoints in <code>x</code> that <code>dyadMember1</code> and <code>dyadMember2</code> were observed to be in contact with one another.
<code>contactStartTime</code>	The timepoint in <code>x</code> at which contact between <code>dyadMember1</code> and <code>dyadMember2</code> begins.
<code>contactEndTime</code>	The timepoint in <code>x</code> at which contact between <code>dyadMember1</code> and <code>dyadMember2</code> ends.

If `blocking == TRUE`, the following columns are appended to the output data frame described above:

<code>block</code>	Integer ID describing unique blocks of time during which contacts occur.
<code>block.start</code>	The timepoint in <code>x</code> at which the block begins.
<code>block.end</code>	The timepoint in <code>x</code> at which the block ends.
<code>numBlocks</code>	Integer describing the total number of time blocks observed within <code>x</code> at which the block

Finally, if `reportParameters == TRUE` function arguments `distThreshold`, `secThreshold`, `equidistant.time`, and `blockLength` (if applicable) will be appended to the output data frame.

**Examples**

```
data(calves)

calves.dateTime<-datetime.append(calves, date = calves$date, time =
  calves$time) #create a dataframe with dateTime identifiers for location foxes

calves.agg<-tempAggregate(calves.dateTime, id = calves.dateTime$calftag,
  dateTime = calves.dateTime$dateTime, point.x = calves.dateTime$x,
  point.y = calves.dateTime$y, secondAgg = 300, extrapolate.left = FALSE,
  extrapolate.right = FALSE, resolutionLevel = "reduced", parallel = FALSE,
  na.rm = TRUE, smooth.type = 1) #smooth locations to 5-min fix intervals.

calves.dist<-dist2All_df(x = calves.agg, parallel = FALSE, dataType = "Point",
  lonlat = FALSE) #calculate distance between all individuals at each timepoint

calves.contact.block<-contactDur.all(x = calves.dist, dist.threshold=1,
  sec.threshold=10, blocking = TRUE, blockUnit = "hours", blockLength = 1,
```

```

equidistant.time = FALSE, parallel = FALSE, reportParameters = TRUE)

calves.contact.Noblock<-contactDur.all(x = calves.dist, dist.threshold=1,
  sec.threshold=10, blocking = FALSE, blockUnit = "hours", blockLength = 1,
  equidistant.time = FALSE, parallel = FALSE, reportParameters = TRUE)

```

---

contactDur.area      *Identify Environmental Contacts*

---

## Description

This function uses the output from dist2Area to determine when tracked individuals are in "contact" with fixed locations. Individuals are said to be in a "contact" event (h) if they are observed within a given distance ( $\leq$  dist.threshold) at a given timestep(i). Sec.threshold dictates the maximum amount of time a single, potential "contact" event should exist. For example, if sec.threshold=10, only "contacts" occurring within 10secs of one another will be regarded as a single "contact" event of duration sum(h). If in this case, a time difference between contacts was 11 seconds, the function will report two separate contact events.

The output of this function is a data frame containing a time-ordered contact edge set detailing animal-environment contacts.

## Usage

```

contactDur.area(
  x,
  dist.threshold = 1,
  sec.threshold = 10,
  blocking = FALSE,
  blockLength = 1,
  blockUnit = "hours",
  blockingStartTime = NULL,
  equidistant.time = FALSE,
  parallel = FALSE,
  nCores = (parallel::detectCores()/2),
  reportParameters = TRUE
)

```

## Arguments

- x                    Output from the dist2Area function (either df or sf variant). Can be either a data frame or non-data-frame list.
- dist.threshold    Numeric. Radial distance (in meters) within which "contact" can be said to occur. Defaults to 1. Note: If you are defining contacts as occurring when polygons intersect, set dist.threshold to 0.
- sec.threshold     Numeric. Dictates the maximum amount of time between concurrent observations during which potential "contact" events remain unbroken. Defaults to 10.

blocking	Logical. If TRUE, contacts will be evaluated for temporal blocks spanning blockLength blockUnit (e.g., 6 hours) within the data set. Defaults to FALSE.
blockLength	Integer. Describes the number blockUnits within each temporal block. Defaults to 1.
blockUnit	Character string taking the values, "secs," "mins," "hours," "days," or "weeks." Describes the temporal unit associated with each block. Defaults to "hours."
blockingStartTime	Character string or date object describing the date OR dateTime starting point of the first time block. For example, if blockingStartTime = "2016-05-01" OR "2016-05-01 00:00:00", the first timeblock would begin at "2016-05-01 00:00:00." If NULL, the blockingStartTime defaults to the minimum dateTime point in x. Note: any blockingStartTime MUST precede or be equivalent to the minimum timepoint in x. Additional note: If blockingStartTime is a character string, it must be in the format ymd OR ymd hms.
equidistant.time	Logical. If TRUE, location fixes in individuals' movement paths are temporally equidistant (e.g., all fix intervals are 30 seconds). Defaults to FALSE. Note: This is a time-saving argument. A sub-function here calculates the time difference (dt) between each location fix. If all fix intervals are identical, it saves a lot of time.
parallel	Logical. If TRUE, sub-functions within the contactDur.all wrapper will be parallelized. Defaults to FALSE.
nCores	Integer. Describes the number of cores to be dedicated to parallel processes. Defaults to half of the maximum number of cores available (i.e., (parallel::detectCores()/2)).
reportParameters	Logical. If TRUE, function argument values will be appended to output data frame(s). Defaults to TRUE.

## Value

Returns a data frame (or list of data frames if x is a list of data frames) with the following columns:

indiv.id	The unique ID of an individual observed in contact with a specified fixed point/polygon.
area.id	The unique ID of a fixed point/polygon observed in contact with indiv.id.
contact.id	The unique ID used to identify contacts between the indiv.id and contact.id pair.
contactDuration	The number of sequential timepoints in x that indiv.id and area.id were observed to be in contact.
contactStartTime	The timepoint in x at which contact between indiv.id and area.id begins.
contactEndTime	The timepoint in x at which contact between indiv.id and area.id ends.

If blocking == TRUE, the following columns are appended to the output data frame described above:

block	Integer ID describing unique blocks of time during which contacts occur.
-------	--

`block.start`      The timepoint in x at which the block begins.  
`block.end`         The timepoint in x at which the block ends.  
`numBlocks`         Integer describing the total number of time blocks observed within x at which the block

Finally, if `reportParameters == TRUE` function arguments `distThreshold`, `secThreshold`, `equidistant.time`, and `blockLength` (if applicable) will be appended to the output data frame.

## Examples

```

data(calves)

calves.dateTime<-datetime.append(calves, date = calves$date,
  time = calves$time) #create a dataframe with dateTime identifiers for location fixes.

calves.agg<-tempAggregate(calves.dateTime, id = calves.dateTime$calftag,
  dateTime = calves.dateTime$dateTime, point.x = calves.dateTime$x,
  point.y = calves.dateTime$y, secondAgg = 300, extrapolate.left = FALSE,
  extrapolate.right = FALSE, resolutionLevel = "reduced", parallel = FALSE,
  na.rm = TRUE, smooth.type = 1) #smooth to 5-min fix intervals.

water<- data.frame(x = c(61.43315, 61.89377, 62.37518, 61.82622),
  y = c(62.44815, 62.73341, 61.93864, 61.67411))

water_poly<-data.frame(matrix(ncol = 8, nrow = 1)) #(ncol = number of vertices)*2 #arrange data
colnum = 0
for(h in 1:nrow(water)){
  water_poly[1,colnum + h] <- water$x[h] #pull the x location for each vertex
  water_poly[1, (colnum + 1 + h)] <- water$y[h] #pull the y location for each vertex
  colnum <- colnum + 1
}

water_dist<-dist2Area_df(x = calves.agg, y = water_poly,
  x.id = calves.agg$id, y.id = "water", dateTime = "dateTime", point.x = calves.agg$x,
  point.y = calves.agg$y, poly.xy = NULL, parallel = FALSE, dataType = "Point",
  lonlat = FALSE, numVertices = NULL) #find distances to the water trough

water_contacts <- contactDur.area(water_dist, dist.threshold=1,
  sec.threshold=10, blocking = FALSE, blockUnit = "mins", blockLength = 10,
  equidistant.time = FALSE, parallel = FALSE, reportParameters = TRUE)

```

---

contactTest

*Determine if Observed Contacts are More or Less Frequent than in a Random Distribution (Defunct)*

---

**Description**

This DEFUNCT function was used to determine if tracked individuals in an empirical dataset had more or fewer contacts with other tracked individuals/specified locations than would be expected at random. The function works by comparing an empirically-based `contactDur.all` or `contactDur.area` function output (`emp.input`) to the `contactDur.all` or `contactDur.area` output generated from randomized data (`rand.input`).

**Usage**

```
contactTest(...)
```

**Arguments**

... Any input will return the error message: "'contactTest' is now defunct. Please consider using another contact-comparison function instead (e.g., [contactCompare\\_chisq](#), [contactCompare\\_mantel](#), etc.)."

**Value**

Always returns the error message: "'contactTest' is now defunct. Please consider using another contact-comparison function instead (e.g., [contactCompare\\_chisq](#), [contactCompare\\_mantel](#), etc.)."

---

dateFake	<i>Create Fake Date Information</i>
----------	-------------------------------------

---

**Description**

This function assigns fake date information, beginning 01/01/startYear, to each empirical timestamp. Users can control what format the output vector is in by changing the `dateFormat` argument (format: "mdy" = month-day-year, "ymd" = year-month-day, "dmy" = day-month-year, or "ydm" = year-day-month).

This is a sub-function that can be found within `datetime.append`.

**Usage**

```
dateFake(timestamp, dateFormat = "mdy", startYear = 2000)
```

**Arguments**

<code>timestamp</code>	Vector of time information with format "hour:minute:second."
<code>dateFormat</code>	Character string. Defines how date information will be presented in output. Takes values "mdy" (i.e., month/day/year), "ymd" (i.e., year/month/day), "dmy" (i.e., day/month/year), or "ydm" (i.e., year/day/month). Defaults to "mdy."
<code>startYear</code>	Numerical. Denotes what year fake date information will begin if <code>dateFake == TRUE</code> . Defaults to 2000.

**Details**

Note that the timestamp argument should be a vector of all relevant timepoints. Additionally, timepoints should be in hms ("hour, minute, second") format.

**Value**

Output is a vector of date values (e.g., "01-1-2000") with length length(timestamp).

**Examples**

```
data("calves")
dateFake(calves$time, dateFormat = "mdy", startYear = 2000)
```

---

 datetime.append

---

*Append Date-Time Information to a Dataset*

---

**Description**

This function appends date-time information to a dataset in POSIXct date\_time format. It also uses functions from the lubridate package and minor calculations to parse out month, day, hour, minute, second, daySecond (the sequentially ordered second of a day), and totalSecond (sequentially ordered second over the course of the study period) of observations in a given dataset with date (format: "mdy" = month/day/year, "ymd" = year/month/day, "dmy" = day/month/year, or "ydm" = year/day/month (note: no preceding zeroes should be included before numbers <10)) and time (format: hour:minute:second (note:preceding zeroes must be included before numbers < 10, ex. 00:00:01)) information, appends this metadata to the dataset, and can assign each day a unique ID.

**Usage**

```
datetime.append(
  x,
  date = NULL,
  time = NULL,
  dateTime = NULL,
  dateFormat = "mdy",
  dateFake = FALSE,
  startYear = 2000,
  tz.in = "UTC",
  tz.out = NULL,
  month = FALSE,
  day = FALSE,
  year = FALSE,
  hour = FALSE,
  minute = FALSE,
  second = FALSE,
  daySecond = FALSE,
```

```

    totalSecond = FALSE
  )

```

### Arguments

x	Data frame or list of data frames to which new information will be appended.
date	Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what date information will be used. If argument == NULL, datetime.append assumes a column with the colname "date" exists in x, or that the dateTime argument != NULL. Defaults to NULL.
time	Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what time information will be used. If argument == NULL, datetime.append assumes a column with the colname "time" exists in x, or that the dateTime argument != NULL. Defaults to NULL.
dateTime	Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what dateTime information will be used. If argument == NULL, date and time arguments must be appropriately defined, OR "date and "time" columns must exist in x. Defaults to NULL.
dateFormat	Character string. Defines how date information is presented. Takes values "mdy" (i.e., month/day/year), "ymd" (i.e., year/month/day), "dmy" (i.e., day/month/year), or "ydm" (i.e., year/day/month). Defaults to "mdy."
dateFake	Logical. If TRUE, the function will assign fake date information, beginning 01/01/startYear, to each of the timestamps. Defaults to FALSE.
startYear	Numerical. Denotes what year fake date information will begin if dateFake == TRUE. Defaults to 2000.
tz.in	Character. Identifies the timezone associated with the time/dateTime argument input. Defaults to "UTC." Timezone names often take the form "Country/City." See the listing of timezones at: <a href="http://en.wikipedia.org/wiki/List_of_tz_database_time_zones">http://en.wikipedia.org/wiki/List_of_tz_database_time_zones</a> .
tz.out	Character. Identifies the timezone that the output dateTime information will be converted to. If NULL, tz.out will be identical to tz.in. Defaults to NULL. Timezone names often take the form "Country/City." See the listing of timezones at: <a href="http://en.wikipedia.org/wiki/List_of_tz_database_time_zones">http://en.wikipedia.org/wiki/List_of_tz_database_time_zones</a> .
month	Logical. If TRUE, output will contain a "month" column with relevant information derived from dateTime information. Defaults to FALSE.
day	Logical. If TRUE, output will contain a "day" column with relevant information derived from dateTime information. Defaults to FALSE.
year	Logical. If TRUE, output will contain a "year" column with relevant information derived from dateTime information. Defaults to FALSE.
hour	Logical. If TRUE, output will contain a "hour" column with relevant information derived from dateTime information. Defaults to FALSE.
minute	Logical. If TRUE, output will contain a "minute" column with relevant information derived from dateTime information. Defaults to FALSE.
second	Logical. If TRUE, output will contain a "second" column with relevant information derived from dateTime information. Defaults to FALSE.

daySecond	Logical. If TRUE, output will contain a "daySecond" column with information detailing what the second of a given day the associated dateTime value corresponds to. Defaults to FALSE.
totalSecond	Logical. If TRUE, output will contain a "totalSecond" column with information detailing what the second of the entire data set the associated dateTime value corresponds to. Defaults to FALSE.

### Value

Output is x with new columns appended according to corresponding arguments.

### Examples

```
data("calves")
calves.dateTime<-datetime.append(calves, date = calves$date, time = calves$time)
head(calves.dateTime) #see now that a dateTime column exists.
```

---

dist2All\_df

*Calculate Distances Between All Individuals*

---

### Description

Calculates the distance between all tracked individuals at a given timestep. Users can choose whether to calculate distances based on a single point, or polygons representative of individuals' locations. If individuals set dataType == "Polygon", the distance matrix reported describes the shortest distances between polygons' edges (Note that the rgeos::gDistance function is used to obtain these distances).

### Usage

```
dist2All_df(
  x = NULL,
  id = NULL,
  dateTime = NULL,
  point.x = NULL,
  point.y = NULL,
  poly.xy = NULL,
  elev = NULL,
  parallel = FALSE,
  nCores = (parallel::detectCores()/2),
  dataType = "Point",
  lonlat = FALSE,
  numVertices = 4
)
```

**Arguments**

x	Data frame or list of data frames containing real-time-location data.
id	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in x, that denotes what unique ids for tracked individuals will be used. If argument == NULL, the function assumes a column with the colname "id" exists in x. Defaults to NULL.
dateTime	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in x, that denotes what dateTime information will be used. If argument == NULL, the function assumes a column with the colname "date-Time" exists in x. Defaults to NULL.
point.x	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in x, that denotes what planar-x or longitude coordinate information will be used. If argument == NULL, the function assumes a column with the colname "x" exists in x. Defaults to NULL.
point.y	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in x, that denotes what planar-y or latitude coordinate information will be used. If argument == NULL, the function assumes a column with the colname "y" exists in x. Defaults to NULL.
poly.xy	Columns within x denoting polygon xy-coordinates. Polygon coordinates must be arranged in the format of those in <code>referencePointToPolygon</code> output. Defaults to NULL.
elev	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in x, that denotes vertical positioning of each individual in 3D space (e.g., elevation). If argument != NULL, relative vertical positioning will be incorporated into distance calculations. Defaults to NULL.
parallel	Logical. If TRUE, sub-functions within the <code>dist2All</code> wrapper will be parallelized. Defaults to FALSE.
nCores	Integer. Describes the number of cores to be dedicated to parallel processes. Defaults to half of the maximum number of cores available (i.e., <code>(parallel::detectCores()/2)</code> ).
dataType	Character string referring to the type of real-time-location data presented in x, taking values of "Point" or "Polygon." If argument == "Point," individuals' locations are drawn from <code>point.x</code> and <code>point.y</code> . If argument == "Polygon," individuals' locations are drawn from <code>poly.xy</code> . Defaults to "Point."
lonlat	Logical. If TRUE, <code>point.x</code> and <code>point.y</code> contain geographic coordinates (i.e., longitude and latitude). If FALSE, <code>point.x</code> and <code>point.y</code> contain planar coordinates. Defaults to FALSE.
numVertices	Numerical. If <code>dataType == "Polygon,"</code> users must specify the number of vertices contained in each polygon. Defaults to 4. Note: all polygons must contain the same number of vertices.

**Details**

If `dataType == "Point,"` users have the option of setting `lonlat == TRUE` (by default `lonlat == FALSE`). `lonlat` is a logical argument that tells the function to calculate the distance between points on the WGS ellipsoid (if `lonlat == TRUE`), or on a plane (`lonlat == FALSE`) (see `raster::pointDistance`).

If `lonlat == TRUE`, coordinates should be in degrees. Otherwise, coordinates should represent planar ('Euclidean') space (e.g. units of meters). This function is not currently able to calculate distances between polygons on the WGS ellipsoid (i.e., if `dataType == "Polygon"`, `lonlat` must = `FALSE`). We aim to address this issue in future versions.

Note that if inputting a separate matrix/dataframe with polygon xy coordinates (`poly.xy`), coordinates must be arranged in the format of those in `referencePointToPolygon` outputs (i.e., `col1 = point1.x`, `col2 = point1.y`, `col3 = point2.x`, `col4 = point2.y`, etc., with points listed in a clockwise (or counter-clockwise) order).

## Value

Returns a data frame (or list of data frames if `x` is a list of data frames) with the following columns:

<code>dateTime</code>	The unique date-time information corresponding to when tracked individuals were observed in <code>x</code> .
<code>totalIndividuals</code>	The total number of individuals observed at least one time within <code>x</code> .
<code>individualsAtTimestep</code>	The number of individuals in <code>x</code> observed at the timepoint described in the <code>dateTime</code> column.
<code>id</code>	The unique ID of a tracked individual for which we will evaluate distances to all other individuals observed in <code>x</code> .
<code>dist.to.indiv_...</code>	The observed distance between the individual described in the <code>id</code> column to every other individual observed at specific timepoints.

## Examples

```
data(calves)

calves.dateTime<-datetime.append(calves, date = calves$date,
  time = calves$time)

calves.agg<-tempAggregate(calves.dateTime, id = calves.dateTime$calftag,
  dateTime = calves.dateTime$dateTime, point.x = calves.dateTime$x,
  point.y = calves.dateTime$y, secondAgg = 300, extrapolate.left = FALSE,
  extrapolate.right = FALSE, resolutionLevel = "reduced", parallel = FALSE,
  na.rm = TRUE, smooth.type = 1) #smooth locations to 5-min fix intervals.

calves.dist2<-dist2All_df(x = calves.agg, parallel = FALSE, dataType = "Point",
  lonlat = FALSE) #calculate distance between all individuals at each timepoint.
```

---

 dist2Area\_df

---

*Calculate Distances Between Individuals and Fixed Points/Polygons*

---

### Description

Calculate distances (either planar or great circle - see dist2All\_df) between each individual, reported in x, and a fixed point(s)/polygon(s), reported in y, at each timestep.

### Usage

```
dist2Area_df(
  x = NULL,
  y = NULL,
  x.id = NULL,
  y.id = NULL,
  dateTime = NULL,
  point.x = NULL,
  point.y = NULL,
  poly.xy = NULL,
  parallel = FALSE,
  nCores = (parallel::detectCores()/2),
  dataType = "Point",
  lonlat = FALSE,
  numVertices = 4
)
```

### Arguments

x	Data frame or list of data frames containing real-time-location data for individuals.
y	Data frame or list of data frames describing fixed-area polygons/points for which we will calculate distances relative to tracked individuals at all time steps. Polygons contained within the same data frame must have the same number of vertices.
x.id	Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what unique ids for tracked individuals will be used. If argument == NULL, the function assumes a column with the colname "id" exists in x. Defaults to NULL.
y.id	Vector of length sum(nrow(data.frame(y[1:length(y)]))) or singular character data, detailing the relevant colname in y, that denotes what unique ids for fixed-area polygons/points will be used. If argument == NULL, the function assumes a column with the colname "id" may exist in y. If such a column does exist, fixed-area polygons will be assigned unique ids based on values in this column. If no such column exists, fixed-area polygons/points will be assigned sequential numbers as unique identifiers. Defaults to NULL.

dateTime	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in <code>x</code> , that denotes what dateTime information will be used. If argument == <code>NULL</code> , the function assumes a column with the colname "dateTime" exists in <code>x</code> . Defaults to <code>NULL</code> .
point.x	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in <code>x</code> , that denotes what planar-x or longitude coordinate information will be used. If argument == <code>NULL</code> , the function assumes a column with the colname "x" exists in <code>x</code> . Defaults to <code>NULL</code> .
point.y	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in <code>x</code> , that denotes what planar-y or latitude coordinate information will be used. If argument == <code>NULL</code> , the function assumes a column with the colname "y" exists in <code>x</code> . Defaults to <code>NULL</code> .
poly.xy	Columns within <code>x</code> denoting polygon xy-coordinates. Polygon coordinates must be arranged in the format of those in <code>referencePointToPolygon</code> output. Defaults to <code>NULL</code> .
parallel	Logical. If <code>TRUE</code> , sub-functions within the <code>dist2Area_df</code> wrapper will be parallelized. Note that this can significantly speed up processing of relatively small data sets, but may cause R to crash due to lack of available memory when attempting to process large datasets. Defaults to <code>FALSE</code> .
nCores	Integer. Describes the number of cores to be dedicated to parallel processes. Defaults to half of the maximum number of cores available (i.e., <code>(parallel::detectCores()/2)</code> ).
dataType	Character string referring to the type of real-time-location data presented in <code>x</code> , taking values of "Point" or "Polygon." If argument == "Point," individuals' locations are drawn from <code>point.x</code> and <code>point.y</code> . If argument == "Polygon," individuals' locations are drawn from <code>poly.xy</code> . Defaults to "Point."
lonlat	Logical. If <code>TRUE</code> , <code>point.x</code> and <code>point.y</code> contain geographic coordinates (i.e., longitude and latitude). If <code>FALSE</code> , <code>point.x</code> and <code>point.y</code> contain planar coordinates. Defaults to <code>FALSE</code> .
numVertices	Numerical. If <code>dataType == "Polygon,"</code> users must specify the number of vertices contained in each polygon described in <code>x</code> . Defaults to 4. Note: all polygons must contain the same number of vertices.

### Details

Polygon coordinates (in both `x` and `y` inputs) must be arranged in the format of those in `referencePointToPolygon` outputs (i.e., `col1 = point1.x`, `col2 = point1.y`, `col3 = point2.x`, `col4 = point2.y`, etc., with points listed in a clockwise (or counter-clockwise) order).

This variant of `dist2Area` requires `x` and `y` inputs to be non-shapefile data.

### Value

Returns a data frame (or list of data frames if `x` is a list of data frames) with the following columns:

dateTime	The unique date-time information corresponding to when tracked individuals were observed in <code>x</code> .
totalIndividuals	The total number of individuals observed at least one time within <code>x</code> .

individualsAtTimestep	The number of individuals in x observed at the timepoint described in the dateTime column.
id	The unique ID of a tracked individual for which we will evaluate distances to all other individuals observed in x.
dist.to...	The observed distance between the individual described in the id column to every each polygon/fix location

## Examples

```

data(calves)

calves.dateTime<-datetime.append(calves, date = calves$date,
  time = calves$time) #create a dataframe with dateTime identifiers for location fixes.

calves.agg<-tempAggregate(calves.dateTime, id = calves.dateTime$calftag,
  dateTime = calves.dateTime$dateTime, point.x = calves.dateTime$x,
  point.y = calves.dateTime$y, secondAgg = 300, extrapolate.left = FALSE,
  extrapolate.right = FALSE, resolutionLevel = "reduced", parallel = FALSE,
  na.rm = TRUE, smooth.type = 1) #smooth to 5-min fix intervals.

water<- data.frame(x = c(61.43315, 61.89377, 62.37518, 61.82622),
  y = c(62.44815, 62.73341, 61.93864, 61.67411)) #delineate water polygon

water_poly<-data.frame(matrix(ncol = 8, nrow = 1)) #make coordinates to dist2Area specifications
colnum = 0
for(h in 1:nrow(water)){
  water_poly[1,colnum + h] <- water$x[h] #pull the x location for each vertex
  water_poly[1, (colnum + 1 + h)] <- water$y[h] #pull the y location for each vertex
  colnum <- colnum + 1
}

water_dist<-dist2Area_df(x = calves.agg, y = water_poly,
  x.id = calves.agg$id, y.id = "water", dateTime = "dateTime", point.x = calves.agg$x,
  point.y = calves.agg$y, poly.xy = NULL, parallel = FALSE, dataType = "Point",
  lonlat = FALSE, numVertices = NULL)

```

---

dt.calc

*Calculate Time Difference Between Relocations*

---

## Description

This function calculates the time difference between relocation events, accounting for individuals' ids. This function has the capability to calculate the differences between sequential timepoints related to two different features (e.g., contactStartTime and contactEndTime) if both dateTime1 and dateTime2 are defined, or just sequential timepoints from a single vector (e.g., contactStartTime) if only dateTime1 is defined.

This is a sub-function contained within contactDur variants and contactTest functions.

**Usage**

```
dt.calc(
  x = NULL,
  id = NULL,
  dateTime1 = NULL,
  dateTime2 = NULL,
  timeUnits = "secs",
  parallel = FALSE,
  nCores = (parallel::detectCores()/2),
  timeStepRelation = 1
)
```

**Arguments**

x	data frame containing time data. If NULL at least dateTime must be defined. Defaults to NULL.
id	Vector of length nrow(data.frame(x)) that denotes what unique ids for tracked individuals will be used. If argument == NULL, the function assumes a column with the colname "id" exists in x. Defaults to NULL.
dateTime1	Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what dateTime information will be used. If argument == NULL, the function assumes a column with the colname "dateTime" exists in x. Defaults to NULL.
dateTime2	Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what dateTime information will be used. If argument == NULL, the function will calculate differences between sequential timepoints in dateTime1. If != NULL, the function will calculate differences between dateTime1 and dateTime2 values. Defaults to NULL.
timeUnits	Character string describing the time unit of calculated differences. It takes the values "secs," "mins," "hours," "days," or "weeks." Defaults to "secs."
parallel	Logical. If TRUE, sub-functions within the dt.calc wrapper will be parallelized. Defaults to FALSE.
nCores	Integer. Describes the number of cores to be dedicated to parallel processes. Defaults to half of the maximum number of cores available (i.e., (parallel::detectCores()/2)).
timeStepRelation	Numerical. Takes the value "1" or "2." If argument == "1," dt values in output represent the difference between time t and time t-1. If argument == "2," dt values in output represent the difference between time t and time t+1. Defaults to 1.

**Value**

Output is a data frame with the following columns

id	The unique ID of a tracked individual.
dt	Time difference between relocation events.
units	Temporal unit defined by timeUnits argument.

## Examples

```
data(calves) #load calves data set
calves.datetime<-datetime.append(calves)
dt<-dt.calc(x = calves.datetime, id = calves.datetime$calftag,
  dateTime1 = calves.datetime$dateTime, dateTime2 = NULL,
  timeUnits = "secs", parallel = FALSE, timeStepRelation = 1)

head(dt)
```

---

 dup

*Identify and Remove Duplicated Data Points*

---

## Description

dup (a.k.a. Multiple instance filter) identifies and removes timepoints when tracked individuals were observed in >1 place concurrently. If `avg == TRUE`, duplicates are replaced by a single row describing an individuals' average location (e.g., planar xy coordinates) during the duplicated time point. If `avg == FALSE`, all duplicated timepoints will be removed, as there is no way for the function to determine which instance among the duplicates should stay. If users are not actually interested in filtering datasets, but rather, determining what observations should be filtered, they may set `filterOutput == FALSE`. By doing so, this function will append a "duplicated" column to the dataset, which reports values that describe if any timepoints in a given individual's path are duplicated. Values are: 0: timepoint is not duplicated, 1: timepoint is duplicated.

## Usage

```
dup(
  x,
  id = NULL,
  point.x = NULL,
  point.y = NULL,
  dateTime = NULL,
  avg = TRUE,
  parallel = FALSE,
  nCores = (parallel::detectCores()/2),
  filterOutput = TRUE
)
```

## Arguments

<code>x</code>	Data frame containing real-time-location data that will be filtered.
<code>id</code>	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in <code>x</code> , that denotes what unique ids for tracked individuals will be used. If argument <code>== NULL</code> , the function assumes a column with the colname "id" exists in <code>x</code> . Defaults to <code>NULL</code> .

<code>point.x</code>	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in <code>x</code> , that denotes what planar-x or longitude coordinate information will be used. If argument == <code>NULL</code> , the function assumes a column with the colname "x" exists in <code>x</code> . Defaults to <code>NULL</code> .
<code>point.y</code>	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in <code>x</code> , that denotes what planar-y or latitude coordinate information will be used. If argument == <code>NULL</code> , the function assumes a column with the colname "y" exists in <code>x</code> . Defaults to <code>NULL</code> .
<code>dateTime</code>	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in <code>x</code> , that denotes what dateTime information will be used. If argument == <code>NULL</code> , the function assumes a column with the colname "dateTime" exists in <code>x</code> . Defaults to <code>NULL</code> .
<code>avg</code>	Logical. If <code>TRUE</code> , <code>point.x</code> and <code>point.y</code> values for duplicated time steps will be averaged, producing a singular point for all time steps in individuals' movement paths. If <code>FALSE</code> , all duplicated time steps wherein individuals were observed in different locations concurrently are removed from the data set.
<code>parallel</code>	Logical. If <code>TRUE</code> , sub-functions within the <code>dup</code> wrapper will be parallelized. This is only relevant if <code>avg == TRUE</code> . Defaults to <code>FALSE</code> .
<code>nCores</code>	Integer. Describes the number of cores to be dedicated to parallel processes. Defaults to the maximum number of cores available (i.e., <code>(parallel::detectCores()/2)</code> ).
<code>filterOutput</code>	Logical. If <code>TRUE</code> , output will be a data frame containing only movement paths with non-duplicated timesteps. If <code>FALSE</code> , no observations are removed and a "duplicated" column is appended to <code>x</code> , detailing if time steps are duplicated (column value == 1), or not (column value == 0). Defaults to <code>TRUE</code> .

### Details

If users want to remove specific duplicated observations, we suggest setting `filterOutput == FALSE`, reviewing what duplicated timepoints exist in individuals' paths, and manually removing observations of interest.

### Value

If `filterOutput == TRUE`, returns `x` less observations at duplicated timepoints.

If `filterOutput == FALSE`, returns `x` appended with a "duplicated" column which reports timepoints are duplicated (column value == 1), or not (column value == 0).

### Examples

```
data(calves2018) #load the data set

calves_dup<- dup(calves2018, id = calves2018$calftag,
  point.x = calves2018$x, point.y = calves2018$y,
  dateTime = calves2018$dateTime, avg = FALSE, parallel = FALSE,
  filterOutput = TRUE) #there were no duplicates to remove in the first place.
```

---

findDistThresh	<i>Identify Point-Based Distance Threshold for Contact</i>
----------------	--

---

### Description

Sample from a multivariate normal distribution to create "in-contact" n point pairs based on real-time-location systems accuracy, and generate a distribution describing observed distances between point pairs.

### Usage

```
findDistThresh(
  n = 1000,
  acc.Dist1 = 0.5,
  acc.Dist2 = NULL,
  pWithin1 = 90,
  pWithin2 = NULL,
  spTh = 0.666
)
```

### Arguments

n	Integer. Number of "in-contact" point-pairs used in the expected-distance distribution(s). Defaults to 1000.
acc.Dist1	Numerical. Accuracy distance for point 1.
acc.Dist2	Numerical. Accuracy distance for point 2. If == NULL, defaults to acc.Dist1 value.
pWithin1	Numerical. Percentage of data points within acc.Dist of true locations for point 1.
pWithin2	Numerical. Percentage of data points within acc.Dist of true locations for point 2. If == NULL, defaults to pWithin1 value.
spTh	Numerical. Pre-determined distance representing biological threshold for contact.

### Details

This function is for adjusting contact-distance thresholds (spTh) to account for positional accuracy of real-time-location systems, assuming random (non-biased) error in location-fix positions relative to true locations. Essentially this function can be used to determine an adjusted spTh value that likely includes the majority of true contacts defined using the initial spTh.

### Value

Output is a list containing 5 named vectors. The first vector describes summary statistics of the simulated distance distribution. The second and third vectors describes varied confidence intervals (50-99 for the simulated distribution). The fourth vector describes adjusted spTh values that will

capture approximately 84, 98, and 100 contacts given the pre-determined spTh value (all calculated using the Empirical rule). Finally, the fifth vector describes the actual observed frequency of captured true contact given the spTh adjustments listed in the fourth vector.

## References

Farthing, T.S., Dawson, D.E., Sanderson, M.W., and Lanzas, C. 2020. Accounting for space and uncertainty in real-time-location- system-derived contact networks. *Ecology and Evolution* 10(11):4702-4715.

## Examples

```
findDistThresh(n = 10, acc.Dist1 = 0.5, acc.Dist2 = NULL,
  pWithin1 = 90, pWithin2 = NULL, spTh = 0.5)
```

---

makePlanar

*Project Geographic Coordinates onto a Plane*

---

## Description

This function converts lon/lat data (decimal degrees) from a geographic coordinate system to planar coordinates using a custom azimuthal equidistant projection, and appends these new coordinates to an input data frame (x). By default, the function assumes longitude and latitude coordinates were produced using the WGS84 datum, but users may change this datum if they wish.

## Usage

```
makePlanar(
  x = NULL,
  x.lon = NULL,
  x.lat = NULL,
  origin.lon = NULL,
  origin.lat = NULL,
  datum = "WGS84"
)
```

## Arguments

x	Data frame or matrix containing geographic data. Defaults to NULL.
x.lon	Vector of length(nrow(x)) or singular character data, detailing the relevant colname in x, that denotes what longitude information will be used. If argument == NULL, makePlanar assumes a column with the colname "lon" exists in x. Defaults to NULL.
x.lat	Vector of length(nrow(x)) or singular character data, detailing the relevant colname in x, that denotes what latitude information will be used. If argument == NULL, makePlanar assumes a column with the colname "lat" exists in x. Defaults to NULL.

origin.lon	Numerical. Describes the longitude will be used as the origin-point longitude for the azimuthal-equidistant projection. If NULL, defaults to the longitude of the data set's centroid. Defaults to NULL.
origin.lat	Numerical. Describes the latitude will be used as the origin-point latitude for the azimuthal-equidistant projection. If NULL, defaults to the latitude of the data set's centroid. Defaults to NULL.
datum	Character string describing the datum used to generate x.lon and x.lat. Defaults to "WGS84."

### Details

Users may specify longitude and latitude coordinates to become the origin of the projection (i.e., the (0,0) coordinate). If they do not specify these values, however, the function calculates the centroid of the data and will use this as the origin point.

Note: this function does not allow any NA coordinate values in longitude/latitude vectors. If NAs exist you will get the following error: "Error in .local(obj, ...) : NA values in coordinates." If NAs exist in your data, we suggest 1.) removing them, or 2.) smoothing data using `contact::tempAggregate` prior to running this function.

### Value

Output is `x` appended with the following columns:

<code>planar.x</code>	Planar x-coordinate values derived from longitude observations.
<code>planar.y</code>	Planar y-coordinate values derived from latitude observations.
<code>origin.lon</code>	Longitude of the origin point, either user specified or the longitude of the data's centroid.
<code>origin.lat</code>	Latitude of the origin point, either user specified or the latitude of the data's centroid.
<code>origin.distance</code>	Linear distance (m) between every point and the origin point.

### Examples

```
data(baboons)

head(baboons) #see that locations are in geographic coordinates

lon.na <- which(is.na(baboons$location.long) == TRUE) #pull row ids of lon NAs
lat.na <- which(is.na(baboons$location.lat) == TRUE) #pull row ids of lat NAs

baboons.naRM <- droplevels(baboons[-unique(c(lon.na, lat.na)),]) #remove NAs

baboons.naRM_planar <- makePlanar(x = baboons.naRM,
  x.lon = baboons.naRM$location.long, x.lat = baboons.naRM$location.lat,
  origin.lon = NULL, origin.lat = NULL, datum = "WGS84") #note no specified origin coords

head(baboons.naRM_planar) #see that planar coordinates are reported
```

**Description**

mps (a.k.a. Meters-per-Second Filter) identifies and removes timepoints when tracked individuals were observed moving faster than a set distance threshold (representing either the great-circle distance between two points a planar distance metric, depending on whether or not `lonlat == TRUE` or `FALSE`, respectively) per second. (i.e., if it is impossible/highly unlikely that individuals moved faster than a given speed (mps), we can assume that any instances when they were observed doing so were the result of erroneous reporting, and should be removed). When running the mps filter, users have the option of setting `lonlat == TRUE` (by default `lonlat == FALSE`). `lonlat` is a logical argument that tells the function to calculate the distance between points on the WGS ellipsoid (if `lonlat == TRUE`), or on a plane (`lonlat == FALSE`) (see `raster::pointDistance`). If `lonlat == TRUE`, coordinates should be in degrees. Otherwise, coordinates should represent planar ('Euclidean') space (e.g. units of meters).

**Usage**

```
mps(
  x,
  id = NULL,
  point.x = NULL,
  point.y = NULL,
  dateTime = NULL,
  mpsThreshold = 10,
  lonlat = FALSE,
  parallel = FALSE,
  nCores = (parallel::detectCores()/2),
  filterOutput = TRUE
)
```

**Arguments**

<code>x</code>	List or data frame containing real-time location data that will be filtered.
<code>id</code>	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in <code>x</code> , that denotes what unique ids for tracked individuals will be used. If argument <code>== NULL</code> , the function assumes a column with the colname "id" exists in <code>x</code> . Defaults to <code>NULL</code> .
<code>point.x</code>	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in <code>x</code> , that denotes what planar-x or longitude coordinate information will be used. If argument <code>== NULL</code> , the function assumes a column with the colname "x" exists in <code>x</code> . Defaults to <code>NULL</code> .
<code>point.y</code>	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in <code>x</code> , that denotes what planar-y or latitude coordinate information will be used. If argument <code>== NULL</code> , the function assumes a column with the colname "y" exists in <code>x</code> . Defaults to <code>NULL</code> .

<code>dateTime</code>	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in <code>x</code> , that denotes what <code>dateTime</code> information will be used. If argument <code>== NULL</code> , the function assumes a column with the colname "date-Time" exists in <code>x</code> . Defaults to <code>NULL</code> .
<code>mpsThreshold</code>	Numerical. Distance (in meters) representing the maximum distance individuals can realistically travel over a single second.
<code>lonlat</code>	Logical. If <code>TRUE</code> , <code>point.x</code> and <code>point.y</code> contain geographic coordinates (i.e., longitude and latitude). If <code>FALSE</code> , <code>point.x</code> and <code>point.y</code> contain planar coordinates. Defaults to <code>FALSE</code> .
<code>parallel</code>	Logical. If <code>TRUE</code> , sub-functions within the <code>mps</code> wrapper will be parallelized. Defaults to <code>FALSE</code> .
<code>nCores</code>	Integer. Describes the number of cores to be dedicated to parallel processes. Defaults to half of the maximum number of cores available (i.e., <code>(parallel::detectCores()/2)</code> ).
<code>filterOutput</code>	Logical. If <code>TRUE</code> , output will be a data frame or list of data frames (depending on whether or not <code>x</code> is a data frame or not) containing only points that adhere to the <code>mpsThreshold</code> rule. If <code>FALSE</code> , no observations are removed and an "mps" column is appended to <code>x</code> , which reports the avg distance per second individuals moved to get from observation <code>i-1</code> to observation <code>i</code> . Defaults to <code>TRUE</code> .

### Details

If users are not actually interested in filtering datasets, but rather determining what observations should be filtered, they may set `filterOutput == FALSE`. By doing so, this function will append up an "mps" column to the dataset, which reports the avg distance per second individuals moved to get from observation `i-1` to observation `i`.

### Value

If `filterOutput == TRUE`, returns `x` less observations representing impossible/unlikely movements.

If `filterOutput == FALSE`, returns `x` appended with an "mps" column which reports the avg distance per second individuals moved to get from observation `i-1` to observation `i`.

### Examples

```
data(calves) #load calves data

calves.dateTime<-datetime.append(calves, date = calves$date,
  time = calves$time) #create a dataframe with dateTime identifiers for location fixes.

calves_filter1 <- mps(x = calves.dateTime, id = calves.dateTime$calftag,
  point.x = calves.dateTime$x, point.y = calves.dateTime$y,
  dateTime = calves.dateTime$dateTime, mpsThreshold = 10, lonlat = FALSE, parallel = FALSE,
  filterOutput = TRUE)
```

---

ntwrkEdges

*Compile List of Network Edges from a Contact Table*

---

### Description

This function takes the output from `contactDur.all` or `contactDur.area` and generates a data frame showing the list of edges in the contact network.

### Usage

```
ntwrkEdges(
  x,
  importBlocks = FALSE,
  removeDuplicates = TRUE,
  parallel = FALSE,
  nCores = (parallel::detectCores()/2)
)
```

### Arguments

<code>x</code>	Output from the <code>contactDur.all</code> or <code>contactDur.area</code> functions. Can be either a data frame or list of data frames.
<code>importBlocks</code>	Logical. If true blocks will be carried over from <code>x</code> input, allowing for time-ordered and time-aggregated network creation. Defaults to FALSE.
<code>removeDuplicates</code>	Logical. If <code>x</code> is from <code>contactDur.all</code> , to-from node pairs in output will be reported twice (i.e., nodes will be listed as both a to- and a from-node). If <code>removeDuplicates == true</code> , duplicated edges are removed. Defaults to TRUE.
<code>parallel</code>	Logical. If TRUE, sub-functions within the <code>ntwrkEdges</code> wrapper will be parallelized. Note that the only sub-functions parallelized here are called ONLY when <code>importBlocks == TRUE</code> , or when <code>x</code> is a list of data frames.
<code>nCores</code>	Integer. Describes the number of cores to be dedicated to parallel processes. Defaults to half of the maximum number of cores available (i.e., <code>(parallel::detectCores()/2)</code> ).

### Value

Output is a data frame with the following columns, and can easily be used as input for `igraph` functions.

<code>from</code>	The "from" nodes in a contact network. Can also be considered "tail" nodes.
<code>to</code>	The "to" nodes in a contact network. Can also be considered "head" nodes.
<code>durations</code>	The duration of each contact reported in <code>x</code> .
<code>block</code>	(if applicable) time block during which reported contacts occurred.

## Examples

```

data("calves")

calves.dateTime<-datetime.append(calves, date = calves$date,
  time = calves$time) #create a dataframe with dateTime identifiers for location fixes.

calves.agg<-tempAggregate(calves.dateTime, id = calves.dateTime$calftag,
  dateTime = calves.dateTime$dateTime, point.x = calves.dateTime$x,
  point.y = calves.dateTime$y, secondAgg = 300, extrapolate.left = FALSE,
  extrapolate.right = FALSE, resolutionLevel = "reduced", parallel = FALSE,
  na.rm = TRUE, smooth.type = 1) #smooth to 5-min fix intervals.

calves.dist<-dist2All_df(x = calves.agg, parallel = FALSE,
  dataType = "Point", lonlat = FALSE) #calculate inter-animal distances at each timepoint.

calves.contact.NOblock<-contactDur.all(x = calves.dist, dist.threshold=1,
  sec.threshold=10, blocking = FALSE, equidistant.time = FALSE,
  parallel = FALSE, reportParameters = TRUE)

calves.edges<-ntwrkEdges(x =calves.contact.NOblock, importBlocks = FALSE,
  removeDuplicates = TRUE)

calves.network1 <- igraph::graph_from_data_frame(d=calves.edges,
  directed=FALSE)

igraph::V(calves.network1)$color<- "orange1"
igraph::V(calves.network1)$size <-13
igraph::E(calves.network1)$width <- calves.edges$duration
igraph::E(calves.network1)$color <- "black"
igraph::plot.igraph(calves.network1, vertex.label.cex=0.4,
  layout = igraph::layout.circle, main = "Inter-Calf Contacts") #plot the network

```

---

potentialDurations      *Identify Potential Contact Durations*

---

## Description

This function uses the output from `dist2...` functions to determine the potential maximum number of direct-contact durations between individuals in a data set. The max number of durations potentially observed is the number of TSWs both individuals (or an individual and fixed area) were simultaneously observed at the same time over the study period/temporal block.

Please note that this function assumes the desired minimum contact duration (MCD), as defined by Dawson et al. (2019), is 1 (i.e., a "contact" occurs when individuals are within a specified distance threshold for a single timestep). In a future version of this function we will aim to increase flexibility by allowing for variable MCD values. For further clarification on the MCD definition and various contact-determination assumptions, please see:

Dawson, D.E., Farthing, T.S., Sanderson, M.W., and Lanzas, C. 2019. Transmission on empirical dynamic contact networks is influenced by data processing decisions. *Epidemics* 26:32-42. <https://doi.org/10.1016/j.epidem.2018.08.003/>

### Usage

```
potentialDurations(
  x,
  blocking = FALSE,
  blockLength = 1,
  blockUnit = "hours",
  blockingStartTime = NULL,
  distFunction = "dist2All_df"
)
```

### Arguments

x	Output from the dist2All or dist2Area function. Can be either a data frame or non-data-frame list.
blocking	Logical. If TRUE, contacts will be evaluated for temporal blocks spanning blockLength blockUnit (e.g., 6 hours) within the data set. Defaults to FALSE.
blockLength	Integer. Describes the number blockUnits within each temporal block. Defaults to 1.
blockUnit	Character string taking the values: "secs," "mins," "hours," "days," or "weeks." Describes the temporal unit associated with each block. Defaults to "hours."
blockingStartTime	Character string or date object describing the date OR dateTime starting point of the first time block. For example, if blockingStartTime = "2016-05-01" OR "2016-05-01 00:00:00", the first timeblock would begin at "2016-05-01 00:00:00." If NULL, the blockingStartTime defaults to the minimum dateTime point in x. Note: any blockingStartTime MUST precede or be equivalent to the minimum timepoint in x. Additional note: If blockingStartTime is a character string, it must be in the format ymd OR ymd hms.
distFunction	Character string taking the values: "dist2All_df", or "dist2Area_df." Describes the contact-package function used to generate x.

### Value

Returns a data frame (or list of data frames if x is a list of data frames) with the following columns:

id	The unique ID of an individual observed in the data set.
potenDegree	The maximum degree possible for individual id based on the number of other individuals observed during the time period.
potenTotalContactDurations	The maximum number of contact durations individual id may experience during the time period.

potenContactDurations\_...

The maximum number of contact durations individual id may experience with each specific individual/fixed area during the time period.

If blocking == TRUE, the following columns are appended to the output data frame described above:

block	Integer ID describing unique blocks of time during which contacts may occur.
block.start	The timepoint in x at which the block begins.
block.end	The timepoint in x at which the block ends.

## Examples

```
data(calves)

calves.dateTime<-datetime.append(calves, date = calves$date, time =
  calves$time) #create a dataframe with dateTime identifiers for location foxes

calves.agg<-tempAggregate(calves.dateTime, id = calves.dateTime$calftag,
  dateTime = calves.dateTime$dateTime, point.x = calves.dateTime$x,
  point.y = calves.dateTime$y, secondAgg = 300, extrapolate.left = FALSE,
  extrapolate.right = FALSE, resolutionLevel = "reduced", parallel = FALSE,
  na.rm = TRUE, smooth.type = 1) #smooth locations to 5-min fix intervals.

calves.dist<-dist2All_df(x = calves.agg, parallel = FALSE, dataType = "Point",
  lonlat = FALSE) #calculate distance between all individuals at each timepoint

calves.potentialContacts<-potentialDurations(x = calves.dist, blocking = FALSE)
```

---

randomizeFeature      *Randomize or Pseudorandomize Categorical Variables*

---

## Description

This function randomizes the values in a given column (or set of columns (i.e., c(colname(x)[1], colname(x)[2])), identified by the "feature" argument in a dataset (x).

## Usage

```
randomizeFeature(
  x,
  feature = NULL,
  shuffle = FALSE,
  maintainDistr = TRUE,
  numRandomizations = 1
)
```

**Arguments**

<code>x</code>	Data frame containing real-time-location data.
<code>feature</code>	Vector of 1 or more column names describing variables in <code>x</code> to be randomized.
<code>shuffle</code>	Logical. If TRUE, unique values will be replaced with another, random unique value from the same distribution with 100 certainty. For example if the values in a "dose" column c(0mg,100mg,300mg) were shuffled, one possible outcome would be: <code>x\$dose.shuff[which(x\$dose == "0mg")] &lt;- 300mg</code> , <code>x\$dose.shuff[which(x\$dose == "100mg")] &lt;- 0mg</code> , and <code>x\$dose.shuff[which(x\$dose == "300mg")] &lt;- 100mg</code> . Defaults to FALSE.
<code>maintainDistr</code>	Logical. If TRUE, the number of each unique value in the column will be maintained in the function output. Otherwise, the function will draw on the initial distribution to assign randomized values, but the specific number of each unique value may not be maintained. Defaults to TRUE.
<code>numRandomizations</code>	Integer. The number of replicate data frames produced in output. Defaults to 1.

**Details**

Note: the `shuffle` argument supercedes the `maintainDistr` argument. Therefore, if `shuffle == TRUE`, the `maintainDistr` argument is irrelevant.

**Value**

Output is `x` appended with columns described below.

<code>...shuff</code>	Randomized value of specified variables.
<code>randomRep</code>	Randomization replicate.

**References**

**Examples**

```
data(calves)

system.time(randomizedValues<-contact::randomizeFeature(x = calves,
  feature = c("calftag", "date"), shuffle = TRUE, maintainDistr = TRUE,
  numRandomizations = 3))

randomizedFrame<-data.frame(randomizedValues[[1]], stringsAsFactors = TRUE)

head(randomizedFrame) #see that randomized-value columns have been appended.
```

---

randomizePaths	<i>Randomize or Pseudorandomize Individuals' Relocation Events</i>
----------------	--

---

### Description

Randomizes or pseudorandomizes individuals' spatial locations. Randomized datasets can later be compared to empirical ones to determine if individuals' space use differ from what would be expected at random (using the contactTest function).

### Usage

```
randomizePaths(
  x = NULL,
  id = NULL,
  dateTime = NULL,
  point.x = NULL,
  point.y = NULL,
  poly.xy = NULL,
  parallel = FALSE,
  nCores = (parallel::detectCores()/2),
  dataType = "Point",
  numVertices = 4,
  blocking = TRUE,
  blockUnit = "hours",
  blockLength = 1,
  shuffle.type = 0,
  shuffleUnit = "days",
  indivPaths = TRUE,
  numRandomizations = 1,
  reduceOutput = FALSE
)
```

### Arguments

x	Data frame containing real-time-location data.
id	Vector of length nrow(x) or singular character data, detailing the relevant colname in x, that denotes what unique ids for tracked individuals will be used. If argument == NULL, the function assumes a column with the colname "id" exists in x. Defaults to NULL.
dateTime	Vector of length nrow(x) or singular character data, detailing the relevant colname in x, that denotes what dateTime information will be used. If argument == NULL, the function assumes a column with the colname "dateTime" exists in x. Defaults to NULL.
point.x	Vector of length nrow(x) or singular character data, detailing the relevant colname in x, that denotes what planar-x or longitude coordinate information will be used. If argument == NULL, the function assumes a column with the colname "x" exists in x. Defaults to NULL.

<code>point.y</code>	Vector of length <code>nrow(x)</code> or singular character data, detailing the relevant colname in <code>x</code> , that denotes what planar-y or latitude coordinate information will be used. If argument <code>== NULL</code> , the function assumes a column with the colname "y" exists in <code>x</code> . Defaults to <code>NULL</code> .
<code>poly.xy</code>	Columns within <code>x</code> denoting polygon xy-coordinates. Polygon coordinates must be arranged in the format of those in <code>referencePointToPolygon</code> output. Defaults to <code>NULL</code> .
<code>parallel</code>	Logical. If <code>TRUE</code> , sub-functions within the <code>randomizePaths</code> wrapper will be parallelized. Defaults to <code>FALSE</code> .
<code>nCores</code>	Integer. Describes the number of cores to be dedicated to parallel processes. Defaults to half of the maximum number of cores available (i.e., <code>(parallel::detectCores()/2)</code> ).
<code>dataType</code>	Character string referring to the type of real-time-location data presented in <code>x</code> , taking values of "Point" or "Polygon." If <code>dataType == "Point"</code> , individuals' locations are drawn from <code>point.x</code> and <code>point.y</code> . If argument <code>== "Polygon"</code> , individuals' locations are drawn from <code>poly.xy</code> . Defaults to "Point."
<code>numVertices</code>	Integer. If <code>dataType == "Polygon"</code> , users must specify the number of vertices contained in each polygon. Defaults to 4. Note: all polygons must contain the same number of vertices.
<code>blocking</code>	Logical. If <code>TRUE</code> , prior to randomization, timepoints will be categorized into a series of temporal blocks of <code>blockLength-blockUnit</code> length (e.g., 10 mins). After generating blocks, the spatial-location randomization methodology will follow <code>shuffle.type</code> . If <code>FALSE</code> , paths will be randomized by sampling from observed timepoints. No timepoints will be represented more than once in the randomized set. Defaults to <code>TRUE</code> .
<code>blockUnit</code>	Integer. Describes the number <code>blockUnits</code> within each temporal block. Defaults to 1.
<code>blockLength</code>	Character string taking the values, "secs," "mins," "hours," "days," or "weeks." Describes the temporal unit associated with each block. Defaults to "hours."
<code>shuffle.type</code>	Integer. Describes which <code>shuffle.type</code> is used to randomize the <code>rand.input</code> data set(s), given that <code>blocking == TRUE</code> (Note: this value is irrelevant if <code>blocking == FALSE</code> ). Takes the values "0," "1," or "2," and defaults to 0. Descriptions of each <code>shuffle.type</code> value can be found under <code>Details</code> .
<code>shuffleUnit</code>	Character string taking the values, "secs," "mins," "hours," "days," or "weeks." Defaults to "days." Describes what temporal unit blocks will be shuffled across given <code>shuffle.type == 2</code> . Blocklength-units may never exceed 1 <code>shuffleUnit</code> (e.g., 25-hour blocks cannot be shuffled using <code>shuffleUnit == "Days,"</code> but 1:24-hour blocks work just fine).
<code>indivPaths</code>	Logical. If <code>TRUE</code> , paths will be randomized with no location switching between ids (e.g., randomized xy locations for individual 1 will be generated by sampling only from individual 1's location distribution). If <code>FALSE</code> , paths will be randomized with potential location switching between ids (e.g., randomized xy locations for individual 1 will be generated by sampling from the entire dataset's location distribution). Defaults to <code>TRUE</code> .
<code>numRandomizations</code>	Integer. The number of replicate data frames produced in output. Defaults to 1.

`reduceOutput` Logical. If TRUE, to reduce output size, only "id," "x.rand," "y.rand," "date-Time," and "rand.rep" columns will be included in function output. Defaults to FALSE.

## Details

Paths can be randomized, or pseudorandomized differently according to what logical arguments are set to TRUE.

Detailed `shuffle.type` description: If `shuffle.type == 0`, within-block timepoints will be randomized by sampling from observed timepoints only within the relevant block (e.g., points in block 1 may be redistributed). Block order in the data set does not change, and no timepoints will be represented more than once in the randomized set. If `shuffle.type == 1`, blocks are shuffled around, but points within blocks are not redistributed (e.g., block 1 <- block 5, block 3 <- block 2, block 5 <- block 4). If `shuffle.type == 2`, blocks are shuffled, but their relative temporal location in the `shuffleUnit` is maintained. For example, there are 144 10-min blocks in a 24-hour day. Say our data set contains 3 days worth of data (i.e., 432 blocks). During the randomization, because blocks maintain their relative locations in `shuffleUnits` (e.g., Days), block 1 in the random set will be determined by sampling from a distribution of blocks 1,145, and 289, which each represent the first block of a given `shuffleUnit` (e.g., Day 1, Day 2, Day 3). All blocks in the randomized set are decided in this fashion (e.g., block 2 of the randomized set is identified by sampling from a distribution of blocks 2, 146, and 290). Therefore, `blocklength-units` may never exceed 1 `shuffleUnit` (e.g., 25-hour blocks cannot be shuffled using `shuffleUnit == "Days,"` but 1:24-hour blocks work just fine). Points within blocks are not redistributed. `Shuffle.types 1 & 2` are both variants of the randomization methodology described by Spiegel et al. 2016.

Note that, if `shuffle.type == 2`, all `dateTime` values in individuals movement paths described in `x` must be equidistant (e.g., relocations for individual `i` occur every 10 seconds), or erroneous date-Times will be reported. If raw `dateTime` values are not equidistant, we recommend using our `tempAggregate` function, with `na.rm == FALSE`, to make it so.

## Value

If `reduceOutput == FALSE`, output is `x` appended with columns described below.

<code>x.rand</code>	Randomized values taken from the <code>point.x</code> argument.
<code>y.rand</code>	Randomized values taken from the <code>point.y</code> argument.
<code>shuffle.type</code>	The value specified by the <code>shuffle.type</code> argument.
<code>rand.rep</code>	Randomization replicate.

If `blocking == TRUE` AND `reduceOutput == FALSE`, the following codes are appended to the output data frame described above:

<code>block</code>	Integer ID describing unique blocks of time during which contacts occur.
<code>block.start</code>	The timepoint in <code>x</code> at which the block begins.
<code>block.end</code>	The timepoint in <code>x</code> at which the block ends.
<code>numBlocks</code>	Integer describing the total number of time blocks observed within <code>x</code> at which the block

`blockLength` Character string describing the length of blocks described by `blockLength` and `blockUnit` arguments.

If `reduceOutput == TRUE`, only `id`, `x.rand`, `y.rand`, `dateTime`, and `rand.rep` will be included in output.

## Examples

```
data(calves)

calves.dateTime<-datetime.append(calves, date = calves$date,
  time = calves$time) #create a dataframe with dateTime identifiers for location fixes.

calves.agg<-tempAggregate(calves.dateTime, id = calves.dateTime$calftag,

  indivPaths = TRUE, numRandomizations = 1)
```

---

referencePoint2Polygon

*Create a Rectangular Polygon Using Planar XY Coordinates*

---

## Description

This function creates a square/rectangular polygon from a single reference point by translating its location multiple times using the same method used in `repositionReferencePoint`. For example, even though calves in our study (see `data(calves2018)`) were only equipped with RFID tags on their left ear. With this function, we can create polygons that account for the total space used by each individual at each time step. This function is different from similar point-to-polygon functions for two reasons: 1.) It does not assume points lie within the center of the polygon. Rather, the reference point must be a corner of the polygon (Note: "UL" denotes that the reference point lies on the upper-left corner of the polygon, "UR" denotes that reference point lies on the upper-right corner of the polygon, "DL"

denotes that reference point lies on the down-left corner of the polygon, "DR" denotes that reference point lies on the down-left corner of the polygon). Note that if you want the reference point to be at the center of the polygon, you can first translate the reference point to a central location on tracked individuals using `repositionReferencePoint`. 2.) Polygon angles/directionality are based on observed movements of tracked individuals or gyroscope data.

### Usage

```
referencePoint2Polygon(
  x = NULL,
  id = NULL,
  dateTime = NULL,
  point.x = NULL,
  point.y = NULL,
  direction = NULL,
  StartLocation = "UL",
  UpDownRepositionLen = 1,
  LeftRightRepositionLen = 1,
  CenterPoint = FALSE,
  MidPoints = FALSE,
  immobThreshold = 0,
  parallel = FALSE,
  nCores = (parallel::detectCores()/2),
  modelOrientation = 90
)
```

### Arguments

<code>x</code>	Data frame or list of data frames containing real-time-location point data.
<code>id</code>	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in <code>x</code> , that denotes what unique ids for tracked individuals will be used. If argument <code>== NULL</code> , the function assumes a column with the colname "id" exists in <code>x</code> . Defaults to <code>NULL</code> .
<code>dateTime</code>	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in <code>x</code> , that denotes what <code>dateTime</code> information will be used. If argument <code>== NULL</code> , the function assumes a column with the colname "date-Time" exists in <code>x</code> . Defaults to <code>NULL</code> .
<code>point.x</code>	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in <code>x</code> , that denotes what planar-x or longitude coordinate information will be used. If argument <code>== NULL</code> , the function assumes a column with the colname "x" exists in <code>x</code> . Defaults to <code>NULL</code> .
<code>point.y</code>	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in <code>x</code> , that denotes what planar-y or latitude coordinate information will be used. If argument <code>== NULL</code> , the function assumes a column with the colname "y" exists in <code>x</code> . Defaults to <code>NULL</code> .
<code>direction</code>	Numerical vector of length <code>nrow(data.frame(x))</code> or singular character data detailing the relevant colname in <code>x</code> , that denotes what movement-direction infor-

mation will be used. Observations in this vector represent the direction (in degrees) that tracked individuals moved to reach their position at each time point, NOT the direction that they will move to reach their subsequent position (i.e., values represent known orientations at each time point). Note that for the purposes of this function, observations of 0, 90, 180, and 270 degrees indicates that an individual moved straight Eastward, Northward, Westward, and Southward, respectively. If NULL, direction will be calculated using observed point-locations. Defaults to NULL.

**StartLocation** Character string taking the values "UL," "UR," "DL," or "DR" describing where the reference point (i.e., point corresponding to xy-coordinates in the data set) lies on the rectangle that this function will delineate. Defaults to "UL."

**UpDownRepositionLen** Numerical. Describes the height, in planar units (e.g., meters) of the output polygon. Planar units are inherent to the real-time-location input. Defaults to 1.

**LeftRightRepositionLen** Numerical. Describes the width, in planar units (e.g., meters) of the output polygon. Planar units are inherent to the real-time-location input. Defaults to 1.

**CenterPoint** Logical. If TRUE, in addition to the xy-coordinates for each polygon vertex, xy-coordinates for centroid of each polygon will be reported in the output. Defaults to FALSE.

**MidPoints** Logical. If TRUE, in addition to the xy-coordinates for each polygon vertex, xy-coordinates for mid-point of each polygon edge will be reported in the output. Defaults to FALSE.

**immobThreshold** Numerical. Describes what we call, the immobility threshold, which is a movement distance (in planar units) within which we assume individuals' physical locations and orientations remain unchanged. This immobility threshold allows us to discount observed movements so miniscule that the majority of animals' physical-space usage is likely unaffected (e.g., head shaking). Defaults to 0.

**parallel** Logical. If TRUE, sub-functions within the referencePoint2Polygon wrapper will be parallelized. Defaults to FALSE.

**nCores** Integer. Describes the number of cores to be dedicated to parallel processes. Defaults to half of the maximum number of cores available (i.e., (parallel::detectCores()/2)).

**modelOrientation** Numerical. Describes the relative orientation (in degrees) of a planar model (see vignette or Farthing et al. in Press (note: when this manuscript is officially published, we will update this citation/reference information)) describing vertex locations relative to tracking-device point-locations. Defaults to 90.

## Details

Currently, this function only supports input data with coordinates representing planar ('Euclidean') space (e.g. units of meters).

In the output, `point1.x` and `point1.y` represent the xy coordinates from the input file. Point2-n coordinates move in a clockwise direction from point1. For example: if point1 is located on the upper left ("UL") corner of the polygon, point2 would be on the upper right corner, point3 on the bottom right, and point 4 on the bottom left.

If distance == NULL, then function will require information (dist, dx, dy) from 2 points on an individual's path to work properly. Because of this, when no gyroscopic data are provided, at least the first point in each individual's path will be removed (the function will report NAs for adjusted locations). Also note that if the distance between an individual's first point in their path and the second one is 0, the function will also report NAs for the second point's adjusted coordinates. The first non-NA values will only be reported for the instance where dist > 0.

Note that populating the direction argument with gyroscopic accelerometer data (or data collected using similar devices) collected concurrently with point-locations allows us to overcome a couple of assumptions associated with using point-locations alone.

First, unless the direction argument is specifically given (i.e., direction != NULL), vertex locations in output are subject to the assumption that dt values are sufficiently small to capture individuals' orientations (i.e., individuals do not face unknown directions inbetween observed relocations). If input was previously processed using tempAggregate with resolutionLevel == "reduced," dt > secondAgg indicates that tracked individuals were missing in the original dataset for a period of time. In this case, the assumption that individuals are facing a given direction because they moved from the previous timepoint may not be accurate. Consider removing these rows (rows following one with dt > secondAgg; remember that dt indicates the time between reported xy coordinates in row i to row i + 1) from your data set.

Second, unless the direction argument is specifically given (i.e., direction != NULL), this function assumes tracked individuals are always forward-facing. This is because by observing only a single point on each individual, we cannot ascertain the true positioning of individuals' bodies. For example, even if we know a point-location moved x distance in a 90-degree direction, from this information alone we cannot determine what direction said individual was facing at the time (e.g., this could be an example of forward, backward, or sideward movement). However, gyroscopic data (or data collected using similar devices) can tell us absolute movement directions, as opposed to relative ones.

## Value

Output is a data frame with the following columns:

id	Unique ID of tracked individuals.
cornerPoint...x	Planar x coordinates of polygon-corner vertices.
cornerPoint...y	Planar y coordinates of polygon-corner vertices.
startLocation	Describes the location of input point-locations in the vertex outputs. see StartLocation argument.
upDownRepositionLength	Describes the vertical movement of point-locations on planar models. see UpDownRepositionLen argument.
leftRightRepositionLength	Describes the horizontal movement of point-locations on planar models. see leftRightRepositionLen argument.
immob	If "0", distance between observed movements is < immobThreshold.
immobThreshold	Returns the value from the immobThreshold argument.

dateTime        Timepoint at which polygons were observed.  
 dt                The time between reported xy coordinates in row *i* to row *i* + 1 in each individuals' movement path.

If MidPoints or CenterPoints == TRUE, additional columns will be appended to output data frame.

## Examples

```
data("calves")
calves.dateTime<-datetime.append(calves, date = calves$date,
  time = calves$time) #add dateTime identifiers for location fixes.

calves.agg<-tempAggregate(calves.dateTime, id = calves.dateTime$calftag,
  dateTime = calves.dateTime$dateTime, point.x = calves.dateTime$x,
  point.y = calves.dateTime$y, secondAgg = 300, extrapolate.left = FALSE,
  extrapolate.right = FALSE, resolutionLevel = "reduced", parallel = FALSE,
  na.rm = TRUE, smooth.type = 1) #smooth to 5-min fix intervals.

calf_heads <- referencePoint2Polygon(x = calves.agg,
  id = calves.agg$id, dateTime = calves.agg$dateTime,
  point.x = calves.agg$x, point.y = calves.agg$y, direction = NULL,
  StartLocation = "DL", UpDownRepositionLen = 0.333, LeftRightRepositionLen = 0.333,
  CenterPoint = FALSE, MidPoints = FALSE, immobThreshold = 0.1, parallel = FALSE,
  modelOrientation = 90)
```

---

repositionReferencePoint

*Move Data Point a Specified Distance*

---

## Description

Translates locations of a single rfid tag/gps transmitter to a different location a fixed distance away, given a known angular offset (in degrees), while maintaining orientations associated with observed movements (see vignette or Farthing et al. in Review (note: when this manuscript is officially published, we will update this citation/reference information)) For example, calves in our study (see calves2018) were equipped with RFID tags on their left ear. With this function, we can move this reference point somewhere else on the body of each individual. This might be done for a number of reasons, but is very useful for use in the referencePoint2Polygon function later on (for delineating polygons representing entire individuals). Currently, this function only supports input data with coordinates representing planar ('Euclidean') space (e.g. units of meters).

**Usage**

```

repositionReferencePoint(
  x = NULL,
  id = NULL,
  dateTime = NULL,
  point.x = NULL,
  point.y = NULL,
  direction = NULL,
  repositionAngle = 0,
  repositionDist = 1,
  immobThreshold = 0,
  parallel = FALSE,
  nCores = (parallel::detectCores()/2),
  modelOrientation = 90
)

```

**Arguments**

<code>x</code>	Data frame or list of data frames containing real-time-location point data.
<code>id</code>	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in <code>x</code> , that denotes what unique ids for tracked individuals will be used. If argument <code>== NULL</code> , the function assumes a column with the colname "id" exists in <code>x</code> . Defaults to <code>NULL</code> .
<code>dateTime</code>	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in <code>x</code> , that denotes what <code>dateTime</code> information will be used. If argument <code>== NULL</code> , the function assumes a column with the colname "date-Time" exists in <code>x</code> . Defaults to <code>NULL</code> .
<code>point.x</code>	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in <code>x</code> , that denotes what planar-x or longitude coordinate information will be used. If argument <code>== NULL</code> , the function assumes a column with the colname "x" exists in <code>x</code> . Defaults to <code>NULL</code> .
<code>point.y</code>	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in <code>x</code> , that denotes what planar-y or latitude coordinate information will be used. If argument <code>== NULL</code> , the function assumes a column with the colname "y" exists in <code>x</code> . Defaults to <code>NULL</code> .
<code>direction</code>	Numerical vector of length <code>nrow(data.frame(x))</code> or singular character data detailing the relevant colname in <code>x</code> , that denotes what movement-direction information will be used. Observations in this vector represent the direction (in degrees) that tracked individuals moved to reach their position at each time point, NOT the direction that they will move to reach their subsequent position (i.e., values represent known orientations at each time point). Note that for the purposes of this function, observations of 0, 90, 180, and 270 degrees indicates that an individual moved straight Eastward, Northward, Westward, and Southward, respectively. If <code>NULL</code> , direction will be calculated using observed point-locations. Defaults to <code>NULL</code> .

<code>repositionAngle</code>	Numerical. Describes the angle (in degrees) between empirical point-locations and the desired vertex location as represented in a planar model (see vignette or Farthing et al. in Review (note: when this manuscript is officially published, we will update this citation/reference information)). Essentially, this is the direction you want new points to be from original points. Note that for the purposes of this function, observations of 0, 90, 180, and 270 degrees indicates that an individual moved straight Eastward, Northward, Westward, and Southward, respectively. Defaults to 0.
<code>repositionDist</code>	Numerical. Describes the distance from the empirical point-locations to desired vertex locations in planar units (e.g., meters) inherent to the real-time-location input. Defaults to 1.
<code>immobThreshold</code>	Numerical. Describes what we call, the immobility threshold, which is a movement distance (in planar units) within which we assume individuals' physical locations and orientations remain unchanged. This immobility threshold allows us to discount observed movements so miniscule that the majority of animals' physical-space usage is likely unaffected (e.g., head shaking). Defaults to 0.
<code>parallel</code>	Logical. If TRUE, sub-functions within the <code>repositionReferencePoint</code> wrapper will be parallelized. Note that this can significantly speed up processing of relatively small data sets, but may cause R to crash due to lack of available memory when attempting to process large datasets. Defaults to FALSE.
<code>nCores</code>	Integer. Describes the number of cores to be dedicated to parallel processes. Defaults to half of the maximum number of cores available (i.e., <code>(parallel::detectCores()/2)</code> ).
<code>modelOrientation</code>	Numerical. Describes the relative orientation (in degrees) of a planar model (see vignette or Farthing et al. in Press (note: when this manuscript is officially published, we will update this citation/reference information)) describing vertex locations relative to tracking-device point-locations. Defaults to 90.

## Details

In this function, if the distance individuals moved was less than/equal to the noted `immobThreshold`, individuals are said to be immobile ("immob"), and their position will not change relative to their previous one. (i.e., you assume that any observed movement less than `immobThreshold` was due to errors or miniscule bodily movements (e.g., head shaking) that are not indicative of actual movement.)

If `distance == NULL`, then function will require information (`dist`, `dx`, `dy`) from 2 points on an individual's path to work properly. Because of this, when no gyroscopic data are provided, at least the first point in each individual's path will be removed (the function will report NAs for adjusted locations). Also note that if the distance between an individual's first point in their path and the second one is 0, the function will also report NAs for the second point's adjusted coordinates. The first non-NA values will only be reported for the instance where `dist > 0`.

Note that populating the `direction` argument with gyroscopic accelerometer data (or data collected using similar devices) collected concurrently with point-locations allows us to overcome a couple of assumptions associated with using point-locations alone.

First, unless the `direction` argument is specifically given (i.e., `direction != NULL`), new point-locations in output are subject to the assumption that `dt` values are sufficiently small to capture

individuals' orientations (i.e., individuals do not face unknown directions inbetween observed relocations). If input was previously processed using tempAggregate with resolutionLevel == "reduced,"  $dt > secondAgg$  indicates that tracked individuals were missing in the original dataset for a period of time. In this case, the assumption that individuals are facing a given direction because they moved from the previous timepoint may not be accurate. Consider removing these rows (rows following one with  $dt > secondAgg$ ; remember that  $dt$  indicates the time between recording xy coordinates in row  $i$  to row  $i + 1$ ) from your data set.

Second, unless the direction argument is specifically given (i.e.,  $direction \neq NULL$ ), this function assumes tracked individuals are always forward-facing. This is because by observing only a single point on each individual, we cannot ascertain the true positioning of individuals' bodies. For example, even if we know a point-location moved  $x$  distance in a 90-degree direction, from this information alone we cannot determine what direction said individual was facing at the time (e.g., this could be an example of forward, backward, or sideward movement). However, gyroscopic data (or data collected using similar devices) can tell us absolute movement directions, as opposed to relative ones.

### Value

Output is a data frame with the following columns:

id	Unique ID of tracked individuals.
x.original	Original x coordinates from input.
y.original	Original y coordinates from input.
distance.original	Original planar distance (m) between point-location $i$ to point-location $i + 1$ .
dx.original	Original difference between point-location x-coordinate $i$ to x-coordinate $i + 1$ .
dy.original	Original difference between point-location y-coordinate $i$ to y-coordinate $i + 1$ .
x.adjusted	Translated x coordinates.
y.adjusted	Translated y coordinates.
dist.adjusted	Planar distance (m) between translated point-location $i$ to translated point-location $i + 1$ .
dx.adjusted	Difference between translated point-location x-coordinate $i$ to translated x-coordinate $i + 1$ .
dy.adjusted	Difference between translated point-location y-coordinate $i$ to translated y-coordinate $i + 1$ .
movementDirection	Describes the angle of movement (in degrees) required to translate point-locations to be congruent with planar-model adjustments.
repositionAngle	Describes the value repositionAngle of the argument.
repositionDist	Describes the value repositionDist of the argument.
immob	If "0", distance between observed movements is $< immobThreshold$ .
immobThreshold	Returns the value from the immobThreshold argument.
dateTime	Timepoint at which polygons were observed.
dt	The time between reported xy coordinates in row $i$ to row $i + 1$ in each individuals' movement path.

## Examples

```
data("calves")
calves.dateTime<-datetime.append(calves, date = calves$date,
  time = calves$time) #create a dataframe with dateTime identifiers for location fixes.

calves.agg<-tempAggregate(calves.dateTime, id = calves.dateTime$calftag,
  dateTime = calves.dateTime$dateTime, point.x = calves.dateTime$x,
  point.y = calves.dateTime$y, secondAgg = 300, extrapolate.left = FALSE,
  extrapolate.right = FALSE, resolutionLevel = "reduced", parallel = FALSE,
  na.rm = TRUE, smooth.type = 1) #smooth to 5-min fix intervals.

leftShoulder.point<-repositionReferencePoint(x = calves.agg,
  id = calves.agg$id, dateTime = calves.agg$dateTime,
  point.x = calves.agg$x, point.y = calves.agg$y, direction = NULL,
  repositionAngle = 180, repositionDist = 0.0835, immobThreshold = 0, parallel = FALSE,
  modelOrientation = 90)
```

---

socialEdges

*Identify Edges in Social Networks*

---

## Description

This function identifies edges in social networks representative of instances where there are greater or fewer contacts than would be expected at random, given a pre-determined p-value threshold for significance (i.e., alpha level).

## Usage

```
socialEdges(x, alpha = 0.05, weight = NULL, removeDuplicates = TRUE)
```

## Arguments

x	A data frame created by a contactCompare function (e.g., contactCompare_chisq).
alpha	Numerical threshold for determining social significance given p-values reported in x. Observations in x with p.values >= alpha will be returned by this function.
weight	Vector of length nrow(data.frame(x)) denoting what information should be carried over from x to the function output (e.g., number of observed contacts). If the weight is not specified, the "weight" in function output is presented as the proportion of total potential contact durations that nodes were observed in contact with one another (in each separate timeblock if applicable).

removeDuplicates

Logical. If removeDuplicates == true, duplicated edges are removed from the output. Defaults to TRUE.

## Details

This function will automatically import defined time blocks if applicable. Furthermore, because this function is intended describe social relationships between individuals, any "totalDegree" and "totalContactDurations" metrics are not included in function output, even if they are present in x.

## Value

Returns a list with three objects

Greater	Data frame of dyads with more contacts than would be expected at random given the chosen alpha level.
Fewer	Data frame of dyads with fewer contacts than would be expected at random given the chosen alpha level.
p.val_threshold	Reports the chosen alpha level.

## Examples

```
data(calves) #load data

```

---

summarizeContacts      *Summarize Contact Events*

---

## Description

This function takes the output from `contactDur.all` or `contactDur.area` and reports the number of durations when tracked individuals are in "contact" with one another (`contactDur.all`) or with specified fixed points/polygons (`contactDur.area`).

## Usage

```

summarizeContacts(
  x,
  importBlocks = FALSE,
  avg = FALSE,
  parallel = FALSE,
  nCores = (parallel::detectCores()/2)
)

```

## Arguments

**x**                      Output from the `contactDur.all` or `contactDur.area` functions. Can be either a data frame or list of data frames.

importBlocks	Logical. If true, each block in x will be analyzed separately. Defaults to FALSE. Note that the "block" column must exist in x.
avg	Logical. If TRUE, summary output from all data frames contained in x will be averaged together. Output will produce an extra data frame containing the mean column values for each id (per block if importBlocks == TRUE). Defaults to FALSE.
parallel	Logical. If TRUE, sub-functions within the summarizeContacts wrapper will be parallelized. Note that the only sub-function parallelized here is called ONLY when importBlocks == TRUE.
nCores	Integer. Describes the number of cores to be dedicated to parallel processes. Defaults to half of the maximum number of cores available (i.e., (parallel::detectCores()/2)).

### Details

If x is a list, and avg == TRUE, this function will produce an extra data frame containing the mean column values for each id (per block if importBlocks == TRUE).

This is a sub-function found within the contactTest and ntwrkEdges function.

### Value

Returns a data frame (or list of data frames if x is a list of data frames) with the following columns:

id	The unique ID of a tracked individual for which we will summarize to all other individuals/fixed locations observed in x.
id	Sum number of individuals/fixed locations observed in contact specific individuals.
id	Sum number of contacts associated with specific individuals.
contactDuration_...	Number of contacts between specific dyads.

If importBlocks == TRUE, the following columns are appended to the output data frame described above:

block	Integer ID describing unique blocks of time during which contacts occur.
block.start	The timepoint in x at which the block begins.
block.end	The timepoint in x at which the block ends.
numBlocks	Integer describing the total number of time blocks observed within x at which the block

### Examples

```
data(calves)

calves.dateTime<-datetime.append(calves, date = calves$date,
  time = calves$time) #create a dataframe with dateTime identifiers for location fixes

calves.agg<-tempAggregate(calves.dateTime, id = calves.dateTime$calftag,
```

```

dateTime = calves.dateTime$dateTime, point.x = calves.dateTime$x,
point.y = calves.dateTime$y, secondAgg = 300, extrapolate.left = FALSE,
extrapolate.right = FALSE, resolutionLevel = "reduced", parallel = FALSE,
na.rm = TRUE, smooth.type = 1) #smooth to 5-min fix intervals.

calves.dist<-dist2All_df(x = calves.agg, parallel = FALSE,
  dataType = "Point", lonlat = FALSE)
calves.contact.block<-contactDur.all(x = calves.dist, dist.threshold=1,

tempAggregate

*Smooth Point-Locations Over Time*

---

## Description

Aggregate location data by secondAgg seconds over the course of each day represented in the dataset. The function smooths xy data forwards (smooth.type == 1) or backwards (smooth.type == 2) according to a data-point-averaging smoothing methodology. As part of the smoothing process, tempAggregate fills in any missing values (either due to a lack of data transmission or faulty prior interpolation). We recognize that this procedure is not sensitive to individual presence at given timesteps (e.g., some individuals may be missing on certain days, hours, etc., and therefore may produce inaccurate location aggregates if days/hours exist where individuals are not present in the dataset (e.g., they were purposefully removed, or moved outside of the monitoring area)). To increase accuracy, package users may specify a resolutionLevel ("full" or "reduced") to process individuals' locations at different resolutions. If resolution == "reduced", if no locations of individuals exist over any secondAgg time block, NAs will be produced for the time points of interest.

This function is based on real-time-location-data-smoothing methods presented by Dawson et al. 2019.

## Usage

```

tempAggregate(
  x = NULL,
  id = NULL,
  point.x = NULL,
  point.y = NULL,
  dateTime = NULL,
  secondAgg = 10,
  extrapolate.left = FALSE,
  extrapolate.right = FALSE,

```

```

    resolutionLevel = "full",
    parallel = FALSE,
    nCores = (parallel::detectCores()/2),
    na.rm = TRUE,
    smooth.type = 1
  )

```

## Arguments

<code>x</code>	Data frame or list of data frames containing real-time-location data.
<code>id</code>	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in <code>x</code> , that denotes what unique ids for tracked individuals will be used. If argument <code>== NULL</code> , the function assumes a column with the colname "id" exists in <code>x</code> . Defaults to <code>NULL</code> .
<code>point.x</code>	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in <code>x</code> , that denotes what planar-x or longitude coordinate information will be used. If argument <code>== NULL</code> , the function assumes a column with the colname "x" exists in <code>x</code> . Defaults to <code>NULL</code> .
<code>point.y</code>	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in <code>x</code> , that denotes what planar-y or latitude coordinate information will be used. If argument <code>== NULL</code> , the function assumes a column with the colname "y" exists in <code>x</code> . Defaults to <code>NULL</code> .
<code>dateTime</code>	Vector of length <code>nrow(data.frame(x))</code> or singular character data, detailing the relevant colname in <code>x</code> , that denotes what <code>dateTime</code> information will be used. If argument <code>== NULL</code> , the function assumes a column with the colname "date-Time" exists in <code>x</code> . Defaults to <code>NULL</code> .
<code>secondAgg</code>	Integer. The number of seconds over which tracked-individuals' location will be averaged. Defaults to 10.
<code>extrapolate.left</code>	Logical. If <code>TRUE</code> , individuals position at time points prior to their first location fix will revert to their first recorded location. If <code>FALSE</code> , NAs will be placed at these time points in individuals' movement paths. Defaults to <code>FALSE</code> .
<code>extrapolate.right</code>	Logical. If <code>TRUE</code> , individuals position at time points following their last location fix will revert to their final recorded location. If <code>FALSE</code> , NAs will be placed at these time points in individuals' movement paths. Defaults to <code>FALSE</code> .
<code>resolutionLevel</code>	Character string taking the value of "full" or "reduced." If "full," if no known locations of individuals exist over any <code>secondAgg</code> time block, xy-coordinates revert to the last-known values for that individual. If "reduced," if no known locations of individuals exist over any <code>secondAgg</code> time block, NAs will be produced for the time blocks of interest. Defaults to "full."
<code>parallel</code>	Logical. If <code>TRUE</code> , sub-functions within the <code>tempAggregate</code> wrapper will be parallelized. Defaults to <code>FALSE</code> .
<code>nCores</code>	Integer. Describes the number of cores to be dedicated to parallel processes. Defaults to half of the maximum number of cores available (i.e., <code>(parallel::detectCores()/2)</code> ).

na.rm	Logical. If TRUE, all unknown locations (i.e., xy-coordinate pairs reported as NAs) will be removed from the output. Defaults to TRUE. Note that if na.rm == FALSE, all aggregated location fixes will be temporally equidistant.
smooth.type	Numerical, taking the values 1 or 2. Indicates the type of smoothing used to average individuals' xy-coordinates. If smooth.type == 1, data are smoothed forwards. If smooth.type == 2, data are smoothed backwards. Defaults to 1.

### Value

Returns a data frame (or list of data frames if x is a list of data frames) with the following columns:

id	The unique ID of tracked individuals.
x	Smoothed x coordinates.
y	Smoothed y coordinates.
dateTime	Timepoint at which smoothed points were observed.

### References

Dawson, D.E., Farthing, T.S., Sanderson, M.W., and Lanzas, C. 2019. Transmission on empirical dynamic contact networks is influenced by data processing decisions. *Epidemics* 26:32-42. <https://doi.org/10.1016/j.epidem.2018.08.003/>

### Examples

```
data("calves")
head(calves) #observe that fix intervals occur ever 4-5 seconds.

calves.dateTime<-datetime.append(calves, date = calves$date,
  time = calves$time) #add dateTime identifiers for location fixes.

calves.agg<-tempAggregate(calves.dateTime, id = calves.dateTime$calftag,
  dateTime = calves.dateTime$dateTime, point.x = calves.dateTime$x,
  point.y = calves.dateTime$y, secondAgg = 300, extrapolate.left = FALSE,
  extrapolate.right = FALSE, resolutionLevel = "reduced", parallel = FALSE,
  na.rm = TRUE, smooth.type = 1) #smooth to 5-min fix intervals.
```

---

timeBlock.append      *Append TimeBlock Information to a Data Frame*

---

### Description

Appends "block," "block.start," "block.end," and "numBlocks" columns to an input data frame (x) with a dateTime (see dateTime.append) column. This allows users to "block" data into blockLength-blockUnit-long (e.g., 10-min-long) temporal blocks. If x == NULL, the function output will be a data frame with "dateTime" and block-related columns.

**Usage**

```
timeBlock.append(
  x = NULL,
  dateTime = NULL,
  blockLength = 1,
  blockUnit = "hours",
  blockingStartTime = NULL
)
```

**Arguments**

x	Data frame containing dateTime information, and to which block information will be appended. if NULL, dateTime input relies solely on the dateTime argument.
dateTime	Vector of length nrow(x) or singular character data, detailing the relevant colname in x, that denotes what dateTime information will be used. If argument == NULL, the function assumes a column with the colname "dateTime" exists in x. Defaults to NULL.
blockLength	Integer. Describes the number of blockUnits within each temporal block. Defaults to 1.
blockUnit	Character string taking the values, "secs," "mins," "hours," "days," or "weeks." Defaults to "hours."
blockingStartTime	Character string or date object describing the date OR dateTime starting point of the first time block. For example, if blockingStartTime = "2016-05-01" OR "2016-05-01 00:00:00", the first timeblock would begin at "2016-05-01 00:00:00." If NULL, the blockingStartTime defaults to the minimum dateTime point in x. Note: any blockingStartTime MUST precede or be equivalent to the minimum timepoint in x. Additional note: If blockingStartTime is a character string, it must be in the format ymd OR ymd hms.

**Details**

This is a sub-function that can be found in the contactDur functions.

**Value**

Appends the following columns to x.

block	Integer ID describing unique blocks of time of pre-specified length.
block.start	The timepoint in x at which the block begins.
block.end	The timepoint in x at which the block ends.
numBlocks	Integer describing the total number of time blocks observed within x at which the block

**Examples**

```
data("calves")
calves.dateTime<-datetime.append(calves, date = calves$date,
  time = calves$time) #add dateTime identifiers for location fixes.
calves.block<-timeBlock.append(x = calves.dateTime,
  dateTime = calves.dateTime$dateTime, blockLength = 10,
  blockUnit = "mins")
head(calves.block) #see that block information has been appended.
```
